ABSTRACT

Aggregate amyloid beta protein1-42 (Aβ1-42) can typically be found in the early stage of Alzheimer’s disease (AD). Aβ1-42 self-assembles and is highly toxic to neurons. Thus, recognizing aggregated Aβ1-42 is very important for elucidation of Aβ1-42 structure and for the diagnosis of AD. In this study, the specificity of the 79-3 monoclonal antibody against soluble aggregate Aβ1-42 was measured by sandwich Enzyme-Linked Immuno Sorbent Assay (ELISA). Eight monoclonal antibodies against both soluble aggregates and amorphous aggregates were used as primary antibodies. Soluble aggregates and amorphous aggregates were used as antigen. As secondary antibody, HRP was labeled with the 79-3 monoclonal antibody. The reactivity of the 79-3 monoclonal antibody against soluble aggregates was confirmed in all combinations, but little reactivity against amorphous aggregates was found. Furthermore, we performed the above sandwich ELISA using the 37-11 antibody, which is reactive against large oval aggregates (LOA) that occur in micro aggregates, instead of the 79-3 antibody. The 77-3 antibody is 1 of the 8 monoclonal antibodies against soluble aggregates; amorphous aggregates were also used as antigen. As secondary antibody, HRP was labeled with the 79-3 monoclonal antibody. The reactivity of the 79-3 monoclonal antibody against soluble aggregates was confirmed in all combinations, but little reactivity against amorphous aggregates was found. Furthermore, we performed the above sandwich ELISA using the 37-11 antibody, which is reactive against large oval aggregates (LOA) that occur in micro aggregates, instead of the 79-3 antibody. The 77-3 antibody is 1 of the 8 monoclonal antibodies against soluble aggregates; amorphous aggregates also reacted with the 37-11 antibody. These results indicated that soluble aggregates are specifically recognized by a combination of different antibodies. The combined use of these antibodies can be applied to the diagnosis of AD and to defining the structure of the Aβ1-42.

Keywords: Aβ1-42; Monoclonal Antibody; Soluble Aggregates; ELISA

1. INTRODUCTION

Amyloid beta protein is 1 of the proteins that cause Alzheimer’s disease. Aβ is produced in the human brain and is a major constituent of senile plaques [1,2]. There are mainly 2 types of Aβ, viz. Aβ1-40 and Aβ1-42. Aβ1-42 shows greater toxicity against neuronal cells than do Aβ1-40 [3]. Aβ1-42 Represents the monomeric form of the protein; it can, however, also form oligomers from these monomers [4].

In solution, Aβ1-42 is aggregated by self-assembly, and various sizes of Aβ1-42 aggregate have been reported. For example, Aβ-derived diffusible ligands (ADDLs) occur as 17 kDa and 42 kDa aggregates [5]. Low molecular weight (LMW) aggregates are oligomers of Aβ1-42 of approximately 14 kDa [6]. The globulomer in which methionine at the N-terminus of Aβ1-42 is displaced, is approximately 64 kDa, while non-displaced globulomers are 38 - 48 kDa [7,8]. Medium-sized aggregates of Aβ1-42, ASPDs, are 158 - 669 kDa, and aggregated Aβ1-42 of 80 - 500 kDa have also been reported [9,10]. In the class of large Aβ1-42 aggregates, there are large oval aggregates (LOA) that contain an added Aβ16-20 (KLVFF) peptide, as well as aggregates of Aβ1-42 that contain an added Fc-KLVFF [11,12]. The Aβ16-20 (KLVFF) peptide binds to the Aβ1-42 β-sheet and inhibits Aβ1-42 fibril formation. Recently, soluble Aβ has been reported to occur during the process of Aβ aggregation, which is more toxic than the fibril and monomer forms [13,14].
Immunostaining are an effective way to capture the causative agent of a disease, and can be used to recognize the structure of \( \text{A}\beta_{1-42} \) by capturing the aggregates of different sizes. It is important that the size of the aggregated \( \text{A}\beta_{1-42} \) is identified in this way [15]. Antibodies against various \( \text{A}\beta_{1-42} \) aggregates have been produced to date. Among the small \( \text{A}\beta_{1-42} \) aggregates, the antibody 6E10 has been used to capture ADDLs and N-Met-\( \text{A}\beta_{1-42} \) globulomers, which form comparatively small oligomers. In the context of medium-sized \( \text{A}\beta_{1-42} \) aggregates, some antibodies have been reported, but it is difficult to produce a specific antibody against aggregates in this size-range.

Here, we prepared soluble aggregates and amorphous aggregates of \( \text{A}\beta_{1-42} \). Soluble aggregates smaller than LOA were recognized by a combination of antibodies against soluble aggregates, those against soluble aggregates and amorphous aggregates, and those against LOA, by sandwich ELISA. This approach allows structural analysis of \( \text{A}\beta_{1-42} \) aggregates and facilitates diagnosis of AD.

2. MATERIALS AND METHODS

2.1. Preparation of Aggregated \( \text{A}\beta_{1-42} \)

\( \text{A}\beta_{1-42} \) was purchased from AnyGen Co. Ltd., Korea. Amorphous aggregates were prepared as follows. A suspension of 0.44 mM \( \text{A}\beta_{1-42} \) was prepared in Milli Q water and incubated for 30 min at 4°C. The solution was prepared in Dulbecco’s PBS without Ca\(^{2+}\) or Mg\(^{2+}\) (Wako, Osaka, Japan) 0.22 mM. To this solution, 2.2 mM of \( \text{A}\beta_{16-20} \) (AnyGen Co. Ltd.) was added and the mixture stirred at 7 rpm for 16 h, at 37°C [11].

For soluble aggregates, \( \text{A}\beta_{1-42} \) (100 µg) was dissolved in 200 µl of 1,1,1,3,3,3-hexafluoro-2-propanol. This solution was incubated for 16 h at 4°C and then incubated for 3 h at 37°C [16]. Thereafter, the solution was lyophilized; these steps were repeated twice. After the final lyophilization, a solution of \( \text{A}\beta_{1-42} \) was prepared at a concentration of 1 mg/ml in Milli Q water.

2.2. Reactivity of Monoclonal Antibodies during the Preparation of Aggregated and Fibrillar \( \text{A}\beta_{1-42} \)

The 79-3 monoclonal antibody against soluble aggregates and the 78-6 monoclonal antibody against soluble aggregate and amorphous aggregate were used. Reactivity of these monoclonal antibodies were assessed during the preparation of aggregated and fibrillar \( \text{A}\beta_{1-42} \). The measurements were carried out every 4 h, up to 24 h.

2.3. ELISA

As primary antibodies, 8 monoclonal antibodies against soluble aggregates and amorphous aggregates were used. These were used to coat 96-well plates (F96 MAX-ISORP NUNC-IMMUNO PLATE; Thermo Fisher SCIENTIFIC Inc. Rochester NY) (100 µl/well, at a concentration of 2 µg/ml). The plates were incubated for 60 min at 37°C and washed with PBS containing 0.05% Tween. Blocking buffer (Immunoblock; DS Pharma Biomedical) were used to coat the 96 well plates (200 µl/well) and incubated for 60 min at 37°C. The plates were washed with PBS containing 0.05% Tween 5 times. Soluble aggregates and aggregates were then used to coated these prepared 96-well plates (100 µl/well at a concentration of 1 µg/ml). The plates were then incubated for 60 min at 37°C, and washed with PBS containing 0.05% Tween 5 times.

As secondary antibodies, the 37-11 and 79-3 antibodies labeled with horse-radish peroxidase (HRP) were used to coat the 96-well plates (100 µl/well at a concentration of 0.144 µg/ml). The plates were incubated for 60 min at 37°C and were washed with PBS containing 0.05% Tween 5 times. Citrate buffer solution (25 ml), containing 10 mg O-phenylalanine dichloride (Sigma-Aldrich, St. Louis, MO) and 30% hydrogen peroxide, was then used to coat the wells (100 µl/well) and the plates were incubated for 20 min at room temperature. Absorbance was then measured using a microplate reader at 492 nm.

3. RESULTS AND DISCUSSION

3.1. Reactivity of the 79-3 and 78-6 Monoclonal Antibodies during Preparation of Aggregated \( \text{A}\beta_{1-42} \)

The size of the amorphous aggregates of \( \text{A}\beta_{1-42} \) in the presence of \( \text{A}\beta_{16-20} \)-containing LOA is 50 - 400 nm. The size of the soluble aggregates is nearly all approximately 50 nm, although some are 300 nm. The reactivity of the 79-3 and 78-6 monoclonal antibodies decreased during preparation of the amorphous aggregate of \( \text{A}\beta_{1-42} \) in the presence of \( \text{A}\beta_{16-20} \)-containing LOA (Figure 1). After 16 h, the reactivity of the 79-3 monoclonal antibody was lower than that of the 78-6 antibody. This result indicated that the 79-3 monoclonal antibody is more specific for the soluble aggregate than the 78-6 monoclonal antibody.

The 78-6 antibody reacts not only with soluble aggregates, but also with amorphous aggregates.

3.2. Measurement of Soluble Aggregates by Sandwich ELISA

To confirm the specificity of the 79-3 monoclonal antibody for soluble aggregates of \( \text{A}\beta_{1-42} \), we performed an evaluation of the specificity of the 79-3 monoclonal ant-
Figure 1. Reactivity of the antibodies 79-3 (○), against soluble aggregates, and 78-6 (●), against soluble aggregates and amorphous aggregates, in the presence of 2.2 mM Aβ16-20.

tbody labeled with HRP against soluble aggregates of Aβ1-42 with that of the 78-6 monoclonal antibody, using sandwich ELISA. As antigen, soluble aggregates and amorphous aggregates were used. As primary antibodies, 72-10, 73-1, 76-3, 80-4, 75-2, 77-3, and 83-3, which react against both soluble aggregates and amorphous aggregates, as does the 78-6 antibody, were used. The reactivity of the 79-3 monoclonal antibody against soluble aggregates was high (Figure 2); on the other hand, the reactivity of the 79-3 monoclonal antibody against amorphous aggregates was low. By combining the different monoclonal antibodies, it was possible to detect a combination of soluble Aβ1-42 aggregates. These results indicated that these 2 types of antibodies have different epitope sites.

The structure and size of soluble aggregates are different from those of amorphous aggregates. 4G8 and 82E1 are specific monoclonal antibodies against the N-terminus of Aβ [17]. 11A1 is a specific monoclonal antibody directed against positions 22 and 23 of Aβ1-42 oligomers [18]. Thus, the 8 monoclonal antibodies used as primary antibodies reacted with Aβ1-42 of various dimensions. The 79-3 monoclonal antibody recognized only soluble aggregates. Therefore, the 79-3 monoclonal antibody recognizes an epitope on the surface of Aβ1-42.

Furthermore, we have attempted to construct a similar sandwich ELISA using the monoclonal antibodies that reacts against LOA other than 79-3, such as 37-11.

HRP was used to label the 37-11 monoclonal antibody, as for 79-3, and the reactivity of the 37-11 antibody was evaluated against those of the 9 monoclonal antibodies that react against soluble aggregates and amorphous aggregates, using sandwich ELISA. These results are shown in Figure 3. The results indicated that a combination of the 37-11 and 77-3 antibodies yielded the highest reactivity, whereas those of the other were low. The 37-11 monoclonal antibody is specific for LOA. However it is possible that the 37-11 antibody could recognize soluble aggregates different from LOA by changing the measurement system of the sandwich ELISA. These results suggested that the epitopes of the 37-11 and 77-3 monoclonal antibodies differ.

In this study, we were able to recognize soluble aggregates by sandwich ELISA. Further refinement of the size of aggregated Aβ1-42 would be possible and may facilitate the analysis of the structure of Aβ1-42 and the diagnosis of AD.

4. ACKNOWLEDGEMENTS

We thank the president of Immuno Probe Co. Ltd., Mr. Hiroshi Nomura, for technical assistance in producing the monoclonal antibodies.
