Abstract

In this paper, we present an algorithm to solve the inequality constrained multi-objective programming (MP) by using a penalty function with objective parameters and constraint penalty parameter. First, the penalty function with objective parameters and constraint penalty parameter for MP and the corresponding unconstraint penalty optimization problem (UPOP) is defined. Under some conditions, a Pareto efficient solution (or a weakly-efficient solution) to UPOP is proved to be a Pareto efficient solution (or a weakly-efficient solution) to MP. The penalty function is proved to be exact under a stable condition. Then, we design an algorithm to solve MP and prove its convergence. Finally, numerical examples show that the algorithm may help decision makers to find a satisfactory solution to MP.

Keywords

Multi-Objective Programming, Penalty Function, Objective Parameters, Constraint Penalty Parameter, Pareto Weakly-Efficient Solution

1. Introduction

Multi-objective programming is an important model in solving vector optimization problems. Many methods had been given to find solutions to multiobjective programming [1]. It is well-known that the penalty function is one of efficient methods in studying multiobjective programming. For example, in 1984, White [2] presented an exact penalty function for multiobjective programming. Sunaga, Mazeed and Kondo [3] applied penalty function

Because it is almost not possible for decision makers (DMs) to obtain all efficient solutions to MP, it is significant to present an efficient algorithm of MP so that DMs finds an easy and satisfactory solution to the MP. Luque, Ruiz and Steuer pointed out that an efficient algorithms not only help decision makers learn more about efficient solutions, but also navigate to a final solution as quickly as possible [12]. This paper presents an algorithm by modifying every objective parameter of penalty function so that a final solution is easily and quickly obtained. In Section 2, we introduce a penalty function with the objective parameters and constraint penalty parameter, and its algorithm. In Section 3, we give numerical results to show that the proposed algorithm is efficient.

2. Penalty Function with Objective Parameters and Constraint Penalty Parameter

In this paper we consider the following inequality constrained multi-objective programming:

\[
\text{(MP)} \quad \min f(x) = \left(f_1(x), f_2(x), \ldots, f_q(x)\right)
\]

\[\text{s.t. } g_i(x) \leq 0, \quad i = 1, 2, \ldots, m, \quad \forall x \in \mathbb{R}^n.\]

where \(f_j: \mathbb{R}^n \to \mathbb{R}^q \cup \{+\infty\}, \quad g_i: \mathbb{R}^n \to \mathbb{R}^m \cup \{+\infty\}, \) for \(j \in J = \{1, 2, \ldots, q\}, i \in I = \{1, 2, \ldots, m\} \).

We denote the feasible set of MP (1) by \(X = \{x \in \mathbb{R}^n | g_i(x) \leq 0, i \in I\}\). As usual, \(x \in X\) is called a Pareto weakly-efficient solution if there is no \(x \in X\) such that \(f_j(x) < f_j(x)\) for all \(j \in J\), i.e. \(f(x) < f(\bar{x})\). \(\bar{x} \in X\) is called a Pareto efficient solution if there is no \(x \in X\) such that \(f_j(x) \leq f_j(\bar{x})\) for all \(j \in J\) and \(f_j(x) < f_j(\bar{x})\) for at least one \(j \in J\), i.e. \(f(x) \leq f(\bar{x})\).

Let functions \(Q: \mathbb{R} \to \mathbb{R}^q \cup \{+\infty\}\) and \(P: \mathbb{R} \to \mathbb{R}^m \cup \{+\infty\}\) satisfy

\[Q(t) = 0 \quad \text{if and only if } \quad t \leq 0,
Q(t) > 0 \quad \text{if and only if } \quad t > 0,
Q(t_2) > Q(t_1) \quad \text{if and only if } \quad t_2 > t_1 > 0,
\]

where \(\lim_{t \to -\infty} Q(t) = 0\) and

\[P(t) = 0 \quad \text{if and only if } \quad t \leq 0,
P(t) > 0 \quad \text{if and only if } \quad t > 0,
P(t_2) > P(t_1) \quad \text{if and only if } \quad t_2 > t_1 > 0.
\]

Let

\[F_j(x, M_j, \rho) = Q(f_j(x) - M_j) + \rho \sum_{i=1}^m P(g_i(x)), \quad j = 1, 2, \ldots, q,
\]

where \(M_j(j = 1, 2, \ldots, q)\) is an objective parameter and \(\rho > 0\) is the constraint penalty parameter. Let \(M = (M_1, M_2, \ldots, M_q)\) and the penalty function of (1) be defined as:
Consider the following unconstrained penalty optimization problem:

\[ \text{MP}(\mathbf{M}, \rho) \quad \min \mathbf{F}(\mathbf{x}, \mathbf{M}, \rho), \quad \text{s.t.} \quad \mathbf{x} \in \mathbb{R}^n. \]

For \( \mathbf{x} \in \mathbb{R}^n \), let index set

\[ J^0(\mathbf{x}, \mathbf{M}, \rho) = \{ j \in J | F_j(\mathbf{x}, \mathbf{M}, \rho) = 0, \text{ for } j \in J \}, \]

\[ J^+(\mathbf{x}, \mathbf{M}, \rho) = \{ j \in J | F_j(\mathbf{x}, \mathbf{M}, \rho) > 0, \text{ for } j \in J \}. \]

We have \( J = J^0(\mathbf{x}, \mathbf{M}, \rho) \cup J^+(\mathbf{x}, \mathbf{M}, \rho) \).

**Theorem 1.** Suppose that for given \( (\mathbf{M}, \rho) \), \( \mathbf{x}^*_M \) is a Pareto weakly-efficient solution to \( \text{MP}(\mathbf{M}, \rho) \). Then the following three assertions hold:

1) If \( J^0(\mathbf{x}^*_M, \mathbf{M}, \rho) \neq \emptyset \), then \( \mathbf{x}^*_M \) is a feasible solution to \( \text{MP} \), \( f_j(\mathbf{x}^*_M) \leq M_j \) for all \( j \in J^0(\mathbf{x}^*_M, \mathbf{M}, \rho) \) and \( f_j(\mathbf{x}^*_M) > M_j \) for all \( j \in J^+(\mathbf{x}^*_M, \mathbf{M}, \rho) \).

2) If \( J^0(\mathbf{x}^*_M, \mathbf{M}, \rho) = \emptyset \) (i.e. \( F(\mathbf{x}^*_M, \mathbf{M}, \rho) > 0 \)), then there is no \( \mathbf{x} \in \mathcal{X} \) such that \( f(\mathbf{x}) < f(\mathbf{x}^*_M) \).

3) If \( F(\mathbf{x}^*_M, \mathbf{M}, \rho) > 0 \) and \( \mathbf{x}^*_M \) is a feasible solution to \( \text{MP} \), then \( \mathbf{x}^*_M \) is a Pareto weakly-efficient solution to \( \text{MP} \).

*Proof.* 1) The conclusion is obvious from the definitions of \( \mathcal{P} \) and \( \mathcal{Q} \).

2) Suppose that there be an \( \mathbf{x} \in \mathcal{X} \) such that \( f(\mathbf{x}) < f(\mathbf{x}^*_M) \). When \( f_j(\mathbf{x}^*_M) \leq M_j \) for some \( j \in J \), we have

\[ Q(f_j(\mathbf{x}) - M_j) = Q(f_j(\mathbf{x}^*_M) - M_j) < Q(f_j(\mathbf{x}^*_M) - M_j) + \rho \sum_{i=1}^m P(g_i(\mathbf{x}^*_M)). \]

When \( f_j(\mathbf{x}^*_M) > M_j \) for some \( j \in J \), we have

\[ Q(f_j(\mathbf{x}) - M_j) < Q(f_j(\mathbf{x}^*_M) - M_j) \leq Q(f_j(\mathbf{x}^*_M) - M_j) + \rho \sum_{i=1}^m P(g_i(\mathbf{x}^*_M)). \]

Hence, \( \mathbf{F}(\mathbf{x}, \mathbf{M}, \rho) < \mathbf{F}(\mathbf{x}^*_M, \mathbf{M}, \rho) \), then \( \mathbf{x}^*_M \) is not a Pareto weakly-efficient solution to \( \text{MP}(\mathbf{M}, \rho) \).

3) According to 2), the conclusion holds.

**Theorem 2.** Suppose that for a given \( (\mathbf{M}, \rho) \), \( \mathbf{x}^*_M \) is a Pareto efficient solution to \( \text{MP}(\mathbf{M}, \rho) \). Then the following three assertions hold:

1) If \( J^0(\mathbf{x}^*_M, \mathbf{M}, \rho) \neq \emptyset \), then \( \mathbf{x}^*_M \) is a feasible solution to \( \text{MP} \), \( f_j(\mathbf{x}^*_M) \leq M_j \) for all \( j \in J^0(\mathbf{x}^*_M, \mathbf{M}, \rho) \) and \( f_j(\mathbf{x}^*_M) > M_j \) for all \( j \in J^+(\mathbf{x}^*_M, \mathbf{M}, \rho) \).

2) If \( J^0(\mathbf{x}^*_M, \mathbf{M}, \rho) = \emptyset \) (i.e. \( F(\mathbf{x}^*_M, \mathbf{M}, \rho) > 0 \)), then there is no \( \mathbf{x} \in \mathcal{X} \) such that \( f(\mathbf{x}) \leq f(\mathbf{x}^*_M) \).

3) If \( F(\mathbf{x}^*_M, \mathbf{M}, \rho) > 0 \) and \( \mathbf{x}^*_M \) is a feasible solution to \( \text{MP} \), then \( \mathbf{x}^*_M \) is a Pareto efficient solution to \( \text{MP} \).

*Proof.* 1) The conclusion is obvious from the definitions of \( \mathcal{P} \) and \( \mathcal{Q} \).

2) Suppose that there be an \( \mathbf{x} \in \mathcal{X} \) such that \( f(\mathbf{x}) \leq f(\mathbf{x}^*_M) \). When \( f_j(\mathbf{x}^*_M) \leq M_j \) for some \( j \in J \), we have

\[ Q(f_j(\mathbf{x}) - M_j) = Q(f_j(\mathbf{x}^*_M) - M_j) < Q(f_j(\mathbf{x}^*_M) - M_j) + \rho \sum_{i=1}^m P(g_i(\mathbf{x}^*_M)). \]

When \( f_j(\mathbf{x}^*_M) > M_j \) for some \( j \in J \), we have
\[ Q(f_j(x) - M_j) \leq Q(f_j(x^*_M) - M_j) \leq Q(f_j(x^*_M) - M_j) + \rho \sum_{i=1}^{\infty} P_i(x^*_M). \]

Hence, \( F(x, M, \rho) \leq F(x^*_M, M, \rho) \), then \( x^*_M \) is not a Pareto efficient solution to \( MP(M, \rho) \).

3) According to 2), the conclusion holds.

Based on Theorem 1, we develop an algorithm to compute an efficient solution to (MP). The algorithm solves the problem \( MP(M, \rho) \) sequentially, and is called Multiobjective Penalty Function Algorithm (MPFA for short).

**MPFA Algorithm:**

Step 1: Choose \( x^0 \in X, \rho_1 > 0, N > 1 \) and \( M_j^* < \min_{x \in X} f_j(x) \) for each \( j \in J \). Let \( k = 1 \), and

\[ M_j^* = \frac{M_j^* + f_j(x^0)}{2} (j \in J). \]

Step 2: Solve \( \min_{x \in R^n} F(x, M^k, \rho_k) \), where \( M^k = (M_1^k, M_2^k, \ldots, M_J^k) \). Let \( x^k \) be a Pareto weakly-efficient solution.

Step 3: If \( J^k = \{ x^k, M^k, \rho_k \} \neq \emptyset \), for each \( j \in J \), let \( M_j^{k+1} = \frac{M_j^k + M_j^*}{2}, \rho_{k+1} = N \rho_k, k+1 := k \) and go to Step 2. Otherwise, \( F(x^k, M^k, \rho_k) > 0 \), go to Step 4.

Step 4: If \( x^k \) is not feasible to (MP), for each \( j \in J \), let \( M_j^{k+1} = \frac{M_j^k + M_j^*}{2}, \rho_{k+1} = N \rho_k, k+1 := k \) and go to Step 2. Otherwise, stop and \( x^k \) is a Pareto weakly-efficient solution to (MP).

In the MPFA algorithm, it is assumed that for each \( j \in J \), \( M_j^* < \min_{x \in X} f_j(x) \) can always be obtained.

The convergence of the MPFA algorithm is proved in the following theorem. For some \( j \in J \), let

\[ S(L, f_j) = \{ x^k | L \geq Q(f_j(x^k) - M_j^k), k = 1, 2, \ldots \}, \]

which is called a Q-level set. \( S(L, f_j) \) is bounded if, for any given \( L > 0 \) and a convergent sequence \( M_j^k \to M_j^* \), \( S(L, f_j) \) is bounded.

**Theorem 3.** Suppose that \( Q, f_j (j \in J) \) and \( g_i (i \in I) \) are continuous on \( R^n \), and the Q-level set \( S(L, f_j) \) is bounded for all \( j \in J \). Let \( \{ x^k \} \) be the sequence generated by the MPFA algorithm.

1) If \( \{ x^k \} \) is a finite sequence (i.e., the MPFA algorithm stops at the \( \bar{k} \)-th iteration), then \( x^k \) is a Pareto weakly-efficient solution to (MP).

2) If \( \{ x^k \} \) is an infinite sequence, then \( \{ x^k \} \) is bounded and any limit point of it is a Pareto weakly-efficient solution to (MP).

**Proof.** For all \( j \in J \), it is clear that the sequence \( \{ M_j^k \} \) decreases with

\[ M_j^{k+1} - M_j^* = \frac{M_j^k - M_j^*}{2}, k = 1, 2, \ldots. \] (2)

Therefore, \( \{ M_j^k \} \) converges to \( M_j^* \) for all \( j \in J \).

1) If the MPFA algorithm terminates at the \( \bar{k} \)-th iteration and the second situation of Step 4 occurs, by Theorem 1, \( x^\bar{k} \) is a Pareto weakly-efficient solution to (MP).

2) We first show that the sequence \( \{ x^k \} \) is bounded. From the MPFA algorithm, we have \( M_j^k < f_j(x) \) for all \( x \in X \). Since \( \{ M_j^k \} \) converges to \( M_j^* \) for all \( j \in J \), there is a \( k' \) such that \( M_j^k < f_j(x) \) for all \( x \in X \) and all \( k > k' \). If \( x^k \in X \) for each \( k > k' \), we have \( Q(f_j(x^k) - M_j^k) > 0 \) for all \( j \in J \). Hence, we
have \( F(x^k, M_k, \rho_k) > 0 \) for all \( k > k' \). By Theorem 1, there is a \( j \in J \) such that
\[
f_j(x^k) \leq f_j(x^0), \quad k = k' + 1, k' + 2, \ldots.
\]
So,
\[
Q(f_j(x^k) - M_j^k) \leq Q(f_j(x^0) - M_j^k), \quad k = k' + 1, k' + 2, \ldots.
\]
Therefore, there is an \( L > 0 \) such that
\[
Q(f_j(x^k) - M_j^k) \leq Q(f_j(x^0) - M_j^k) < L, \quad k = 1, 2, \ldots.
\]
Since \( S(L, f_j) \) is bounded, the sequence \( \{x^k\} \) is bounded. Without loss of generality, we assume \( x^k \to x^* \). Since \( x^k \) is a Pareto weakly-efficient solution to \( MP(M_k, \rho_k) \), for some \( j \), there are infinite \( k > k' \) such that
\[
Q(f_j(x^k) - M_j^k) + \rho_k \sum_{i=1}^m P(g_i(x^k)) \leq Q(f_j(x^0) - M_j^k).
\]
We have
\[
\sum_{i=1}^m P(g_i(x^k)) \leq \frac{1}{\rho_k} \left[ Q(f_j(x^0) - M_j^k) - Q(f_j(x^k) - M_j^k) \right].
\]
When \( \rho_k \to +\infty \), we have \( \sum_{i=1}^m P(g_i(x^k)) = 0 \). Hence, \( x^* \in X \). If \( x^* \) is not a Pareto weakly-efficient solution to (MP), there is an \( x \in X \) such that \( f(x) < f(x^*) \). Let \( \delta = \min \{f_j(x^*) - f_j(x) \mid j = 1, 2, \ldots, q\} \).
From \( x^k \to x^* \), there is some \( k \) such that
\[
f_j(x^*) - f_j(x) < \delta \leq f_j(x^*) - f_j(x), \quad j = 1, 2, \ldots, q.
\]
So, we have \( f(x) < f(x^k) \), which by Theorem 1 is a contradiction. Hence, \( x^* \) is a Pareto weakly-efficient solution to (MP).

Theorem 3 means that the MPFA algorithm is convergent in theory. Now, we discuss the exactness of the penalty function for (MP). If there are an \( M' \in \mathbb{R}^q \) and \( \rho' \) such that a Pareto weakly-efficient solution \( x^* \) to (MP) is also a Pareto weakly-efficient solution to \( P(M, \rho) \) for all \( M < M' \) and \( \forall \rho > \rho' \), then \( F(x, M, \rho) \) is called an exact penalty function.

Let (MP(s)) be a perturbed problem of (MP) given by
\[
(MP(s)) \quad \min f(x) = (f_1(x), f_2(x), \ldots, f_q(x))
\text{ s.t. } g_i(x) \leq s_i, \quad i = 1, 2, \ldots, m,
\]
where \( s = (s_1, s_2, \ldots, s_m) \). Similar to that for a constrained penalty function in [12], we define stability.

**Definition 1.** Let \( x \) be any feasible solution to (MP) and \( x_s \) any feasible solution to (MP(s)) for each \( s \in \mathbb{R}^m \). If there is an \( M' \) such that for \( \forall f \in J \)
\[
\frac{Q(f_j(x) - M_j) - Q(f_j(x^s) - M_j)}{\rho} \leq \|s\|_\rho, \quad \forall M < M' \text{ and } \forall \rho > \rho'
\]
where \( \|s\|_\rho = \sum_{i=1}^m P(s_i) \), then (MP) is stable.

We have an exact result of the penalty function.

**Theorem 4.** Let \( x^* \) be an optimal solution to (MP). If (MP) is stable, \( F(x, M, \rho) \) is an exact penalty function.
Proof. Suppose that $F(x, M_{\rho})$ is not an exact penalty function. Let $x'$ be a Pareto weakly-efficient solution to (MP(s)). According to the definition of stability, we obtain that there is an $M'_{\rho}$ satisfying

$$Q(f_j(x) - M_j) - Q(f_j(x_{*}) - M_j) \leq [s_{i}']_{\rho}, \quad \forall M < M'_{\rho} \text{ and } \forall \rho > \rho' \quad (4)$$

This implies that there is some $M' < M'_{\rho}$ such that $f_j(x') > M'_j$ for $\forall j \in J$. Then, there always exists some $M < M'$ such that $x'$ is not a Pareto weakly-efficient solution to (MP(M)), i.e. there is some $x'$ such that

$$F_j(x', M_j, \rho) < F_j(x_{*}, M_j, \rho) = Q(f_j(x_{*}) - M_j), \quad \forall j \in J.$$

Thus,

$$Q(f_j(x') - M_j) + \rho \sum_{t=1}^{T} P'(g_t(x')) < Q(f_j(x_{*}) - M_j), \quad \forall j \in J.$$

Suppose that $x'$ is a feasible solution to (MP). If $f_j(x') < M_j$ for $j \in J$, we have $f_j(x') < M'_j < f_j(x')$. Otherwise if $f_j(x') \geq M_j$ for $j \in J$, from $Q(f_j(x') - M_j) < Q(f_j(x_{*}) - M_j)$, $f_j(x') < f_j(x')$, which shows that $x'$ is not a Pareto weakly-efficient solution to (MP(M)). A contradiction occurs. Hence, $x'$ is not a feasible solution to (MP) and $\sum_{t=1}^{T} P(f_t(x')) > 0$.

Let $s' = (s'_1, s'_2, \ldots, s'_m)^T$ with $s'_i = g_i(x')$, $i = 1, 2, \ldots, m$, and $x'_i$ be a Pareto weakly-efficient solution to (P(s')). Then, there is some $j$ such that $f_j(x'_i) \leq f_j(x')$ and $f_j(x'_i) - M_j \leq f_j(x') - M_j$. Thus,

$$Q(f_j(x'_i) - M_j) \leq Q(f_j(x') - M_j).$$

Therefore,

$$Q(f_j(x') - M_j) + \rho \sum_{t=1}^{T} P(s'_t) \leq Q(f_j(x') - M_j) + \rho \sum_{t=1}^{T} P(s'_t) = F_j(x', M_j, \rho) < Q(f_j(x_{*}) - M_j),$$

which shows that

$$Q(f_j(x') - M_j) - Q(f_j(x_{*}) - M_j) \geq \rho^*[s'_1]_{\rho},$$

where $[s'_1]_{\rho} = \sum_{t=1}^{T} P(s'_t)$. This inequality contradicts to (4). Hence, (MP) is stable which yields a contradiction with the assumption and proves that $F(x, M_{\rho})$ is an exact penalty function.

3. Numerical Examples

In the MPFA algorithm, it is not easy to solve multiobjective problem $\min_{x \in \mathbb{R}^n} F(x, M_{\rho_i})$. Let

$$\bar{F}(x, M_{\rho}) = F_1(x, M_{\rho_1}) + F_2(x, M_{\rho_2}) + \cdots + F_q(x, M_{\rho_q}).$$

It is easily known that an optimal solution to the problem $\min_{x \in \mathbb{R}^n} \bar{F}(x, M_{\rho_i})$ is a Pareto weakly-efficient solutions to the problem $\min_{x \in \mathbb{R}^n} F(x, M_{\rho_i})$. Hence, we replace the problem $\min_{x \in \mathbb{R}^n} F(x, M_{\rho_i})$ in the Step 2 of the MPFA algorithm with the problem $\min_{x \in \mathbb{R}^n} \bar{F}(x, M_{\rho_i})$. Let $Q'(i) > 0$ for $i > 0$. When $M_j < f_j(x)$, we have
\[
\frac{\partial \bar{F}(x, M_j, \rho)}{\partial M_j} = \frac{\partial F_j(x, M_j, \rho)}{\partial M_j} = -Q'(f_j(x) - M_j) < 0.
\]

Hence, when \( M_j \) decreases, the \( j \)-th objective \( F_j(x, M_j, \rho) \) will decrease too. For fixed \((x, M_i, \rho) (\text{each } i \in J) (i \neq j)\),
\[
\lim_{M_j \to -\infty} F_j(x, M_j, \rho) = 0.
\]

So, we may obtain different Pareto weakly-efficient solutions at given different \((M_i, M_j, \ldots, M_q)\). By controlling \( M_j \), we can control the \( j \)-th objective value \( F_j(x, M_j, \rho) \).

We have applied the MPFA algorithm to several examples programmed by Matlab 6.5. The aim of numerical examples is to check the convergence of the algorithm and to control changes in objectives.

**Example 1.** Consider the following problem:

\[
(P1) \quad \min_{x_1, x_2} f(x_1, x_2) = \{ -2x_1^4 - x_2^4 + 4x_2^4 \}
\]

s.t. \( 2x_1 + 3x_2 \leq 6, -x_1 \leq 0, -x_2 \leq 0 \).

Let penalty function
\[
\bar{F}(x, M, \rho) = \max \{ -2x_1^4 - x_2^4 - M_1, 0 \}^2 + \max \{ x_1^4 + 4x_2^4 - M_2, 0 \}^2
\]
\[
+ \rho \max \{ 2x_1 + 3x_2 - 6, 0 \}^2 + \rho \max \{ -x_1, 0 \}^2 + \rho \max \{ -x_2, 0 \}^2.
\]

Let the starting point \((x_1^0, x_2^0) = (0,0), \ \rho = 1000, \ N = 100\) and constraint error
\[
e(x) = \max \{ 2x_1 + 3x_2 - 6, 0 \} + \max \{ -x_1, 0 \} + \max \{ -x_2, 0 \}.
\]

Clearly, if \( e(x) = 0 \), \( x \) is a feasible solution. We take different parameters \((M_1^*, M_2^*)\) in the MPFA algorithm, the results are shown in Table 1.

In Table 1, when \( M_1 \) or \( M_2 \) decreases, the first objective value \( f_1(x_1, x_2) \) or \( f_2(x_1, x_2) \) decrease too.

Objective parameter can control change of each objective function. It helps decision makers learn about the change of each objective function and choose a satisfactory solution as quickly as possible.

**Example 2.** Consider the problem:

\[
(P2) \quad \min_{x_1, x_2} f(x_1, x_2) = \{ x_1 - 2x_2, -2x_1 + x_2, -x_1 - x_2 \}
\]

s.t. \( x_1 \leq 2x_1^4 - 8x_1^2 + 8x_2^2 + 2 \)
\( x_2 \leq 4x_1^4 - 32x_1^3 + 88x_2^2 - 96x_1 + 36 \)
\( 0 \leq x_1 \leq 3 \)
\( 0 \leq x_2 \leq 4 \)

We want to find a solution that three objectives are as small as possible with the first and second objective value less than \(-2\) and the third objective value less than \(-5\).

Let penalty function
\[
\bar{F}(x, M, \rho) = \max \{ x_1 - 2x_2 - M_1, 0 \}^2 + \max \{ -2x_1 + x_2 - M_2, 0 \}^2 + \max \{ -x_1 - x_2 - M_3, 0 \}^2
\]
\[
+ \rho \max \{ x_1 - 3, 0 \}^2 + \rho \max \{ x_1 - 4, 0 \}^2 + \rho \max \{ -x_1, 0 \}^2 + \rho \max \{ -x_2, 0 \}^2.
\]

Let the starting point \((x_1^0, x_2^0) = (0,0), \ \rho = 1000, \ N = 100\) and constraint error
Table 1. Numerical results with different objective parameters.

$e(x) = \max \{ x_2 - 2x_1^3 + 8x_1 - 8x_2^2 - 2, 0 \} + \max \{ x_1 - 3, 0 \} + \max \{ x_3 - 4, 0 \} + \max \{ -x_1, 0 \} + \max \{ -x_2, 0 \}.$

We take different parameters $(M^*_1, M^*_2, M^*_3)$ in the MPFA algorithm and get the results shown in Table 2.

In Table 2, we find a satisfactory solution $(x_1, x_2) = (2.444095, 2.577823)$ when taking different $(M^*_1, M^*_2, M^*_3)$.

4. Conclusion

In this paper, we define a penalty function with objective parameters and constraint penalty parameter for MP and the corresponding unconstraint penalty optimization problem. Under some conditions, we prove that a Pareto efficient solution (or a weakly-efficient solution) to UPOP is a Pareto efficient solution (or a weakly-efficient solution) to MP, and the penalty function is exact under a stable condition. We present the MPFA algorithm to solve the multi-objective programming with inequality constraints by using the nonlinear penalty function with objective parameters. With this algorithm, we may find a satisfactory solution.
