Abstract

In this paper, an analytical solution for the rotation problem of an inhomogeneous hollow cylinder with variable thickness under plane strain assumption is developed. The present cylinder is made of a fiber-reinforced viscoelastic inhomogeneous orthotropic material. The thickness of the cylinder is taken as parabolic function in the radial direction. The elastic properties varies in the same manner as the thickness of the cylinder while the density varies according to an exponential law form. The inner and outer surfaces of the cylinder are considered to have combinations of free and clamped boundary conditions. Analytical solutions are given according to different types of the hollow cylinders. An extension of the present solutions to the viscoelastic ones and some applications are investigated in Part II.

Keywords: Rotating, Inhomogeneous Cylinders, Orthotropic, Variable Thickness and Density

1. Introduction

The rotation problem of inhomogeneous cylinder has been important applications, particularly in mechanical engineering, aerospace industry, underwater vehicles and biomechanics. The pertinent literature on the investigation of stresses and displacements in an inhomogeneous hollow circular cylinder may be reviewed here. The plane strain problem of a rotating inhomogeneous orthotropic hollow cylinder is solved by Senitskii [1]. Horgan and Chan [2] analyzed two-dimensional plane stress/strain deformations by assuming Young’s modulus to be a power law function of the radial direction of the cylinder and constant Poisson's ratio. Vasilenko and Klimenko, [3] have analyzed the stress state of a rotating cylinder, inhomogeneous in the radial direction, having one plane of elastic symmetry and loaded with centrifugal forces. Rooney and Ferrari [4] have examined the tension, bending, and flexure of cylinders with functionally graded (FG) cross-section. The effect of inhomogeneity of elastic properties and density in the circumferential direction on the distribution of stress and displacement in orthotropic cylindrical panels using load in the axial direction is investigated by Grigorenko and Vasilenko [5]. Oral and Anlas [6] have analyzed the effect of continuous inhomogeneity on the stress distribution in an anisotropic cylinder. Pan and Roy [7] have solved a plane-strain problem for a FG cylinder by dividing it into several homogeneous cylinders. Tutuncu [8] has gave the power series solution for stresses and displacements in FG cylinders with exponentially-varying elastic modulus through the radial direction. Theotokoglou and Stamouloglou [9] have studied axisymmetric problems for radially inhomogeneous circular cylinders. The effect of varying Poisson’s ratio on deformation fields in FG cylinders has been investigated by Mohammadi and Dryden [10]. Li and Peng [11] have analyzed axisymmetric deformations of FG hollow cylinders and disks with arbitrarily varying material properties.

In recent years considerable attention has been given to solutions for the cylinders with variable thickness. Variable-thickness hollow cylinder is a common structure type which can be used in some applications involving aerospace, submarine structures, nuclear reactors as well as chemical pipes. Grigorenko and Rozhok [12] have studied the stress problem for non-circular hollow cylinder with variable thickness under uniform and local loads. Zenkour [13] has established the stresses in a rotating variable-thickness orthotropic cylinder containing a solid core of uniform-thickness. Also, Zenkour [14] has analytically investigated the behavior of composite circular cylinders subjected to internal and ex-
ternal surface loading. The cylinder consists of a number of homogeneous ply groups of axially variable thickness. Duan and Koh [15] have derived analytical solutions for axisymmetric transverse vibration of cylindrical shells with thickness varying monotonically in arbitrary power form due to forces acting in the transverse direction. Nie and Batra [16] have studied plane-strain static deformations of a cylinder with elliptical inner and circular outer surfaces composed of a material that is polar-orthotropic and its moduli vary exponentially in the radial direction.

In this paper, the rotating fiber-reinforced viscoelastic hollow cylinder is analytically studied. The thickness of the cylinder, the elastic properties and density are taken to be functions in the radial coordinate. The governing second-order differential equation is derived and solved with the aid of some hypergeometric functions. The displacement and stresses for rotating variable-thickness inhomogeneous orthotropic hollow cylinder subjected to various boundary conditions are obtained. Special cases of the studied problem are established.

2. Formulation of the Problem

Consider an elastic hollow cylinder made of an inhomogeneous, orthotropic material and rotates about its axis. The cylindrical coordinates \((r, \theta, z)\) are chosen such that the axial coordinate \(z\) coinciding with the axis of rotation, \(r\) is the radial coordinate. Assuming the cylinder is symmetric with respect to the \(z\)-axis, we have only the radial displacement \(u\) which is independent of the circumferential coordinate \(\theta\). Furthermore, in the planes perpendicular to the \(z\)-axis in plane strain, \(u\) is a function of \(r\) alone. Consequently, the Cauchy’s relations under considerations can be written in the following form:

\[
e_{rr} = \frac{du}{dr}, \quad e_{\theta\theta} = \frac{u}{r}, \quad e_{zz} = e_{r\theta} = e_{\theta z} = e_{\theta \theta} = 0, \quad (1)
\]

where \(e_{ij}\) are the strain components.

From the generalized Hooke’s law and using the above geometric relations, we can obtain the stress components for an orthotropic cylinder in the following form:

\[
\begin{align*}
\sigma_{rr} &= c_{11} \frac{du}{dr} + c_{12} \frac{u}{r}, & \sigma_{\theta\theta} &= c_{12} \frac{du}{dr} + c_{22} \frac{u}{r} \\
\sigma_{zz} &= c_{13} \frac{du}{dr} + c_{23} \frac{u}{r}, & \sigma_{r\theta} = \sigma_{\theta z} = \sigma_{\theta \theta} &= 0
\end{align*}
\]

(2)

where \(c_{ij}\) are the elastic properties. Let us assume now that the thickness \(h\) of the cylinder varies in the radial direction in a parabolic form given by:

\[
h(r) = h_0 \left[1 - n (r/b)^k\right], \quad 0 \leq n < 1, \quad k > 0,
\]

(3)

where \(h_0\) is the thickness at the axis of the cylinder, \(n\) and \(k\) are geometric parameters and \(b\) is the external radius of the cylinder. The parameter \(k\) determines the shape of the thickness profile while \(n\) determines the thickness at the surface of the cylinder relative to \(h_0\).

For three sets of geometric parameters \(n\) and \(k\), the dimensionless thickness \(h/h_0\) as a function of the dimensionless radius \(r/b\) is described by the profiles shown in Figure 1 for \(b = 5a\) in which \(a\) is the inner radius of the cylinder. In Figure 1(a) the thickness profile is concave for \(k < 1\) while in Figures. 1(b) and 1(c) it is convex for \(k > 1\). Furthermore, the thickness of the cylinder is linearly decreasing by setting \(k = 1\).

As the effect of thickness variation of rotating cylinders can be taken into account in their equilibrium equation, the theory of the cylinders of variable thickness can give excellent results as that of the uniform thickness.

![Figure 1. Parabolic cylinder profiles: (a) k = 0.6; n = 0.8; (b) k = 2.5; n = 0.8; (c) k = 2.5; n = 0.4.](image-url)

3. Elastic Solution

Substituting from Equation (2) into Equation (4) with the aid of the expressions given in Equation (5) and the cylinder profile given in Equation (3), we can get the following confluent hypergeometric differential equation for the radial displacement \( u(r) \):

\[
\frac{d^2 u}{dr^2} + r \frac{d u}{dr} - \frac{1 - 2nk(r/b)^k}{1 - n(r/b)^k} \lambda^2 + \frac{2n\mu k(r/b)^k}{1 - n(r/b)^k} u + \frac{\partial\Omega^2 r^3 e^{-m(r/b)^k}}{\alpha_1(1 - n(r/b)^k)} = 0,
\]

where \( \lambda \) and \( \mu \) are arbitrary integration constants and
\[
P_1(\varpi) = \pi^{1/2} M \left( i, j, \delta, n\pi^k \right),
\]
\[
P_2(\varpi) = \pi^{1/2} M \left( i - \delta + 1, j - \delta + 1, 2 - \delta, n\pi^k \right),
\]
in which

\[
R(\varpi) = U_1(\varpi)P_1(\varpi) + U_2(\varpi)P_2(\varpi),
\]

where
\[
\frac{d\Omega^2 r^3 e^{-m(r/b)^k}}{\alpha_1(1 - n(r/b)^k)} = 0,
\]

Note that, the first derivative of the general hypergeometric function is given by:
\[
\frac{\partial\Omega^2 r^3 e^{-m(r/b)^k}}{\alpha_1(1 - n(r/b)^k)} = 0,
\]

where \( \partial_1 \) and \( \partial_2 \) are arbitrary integration constants and
\[
P_1(\varpi) = \pi^{1/2} M \left( i, j, \delta, n\pi^k \right),
\]
\[
P_2(\varpi) = \pi^{1/2} M \left( i - \delta + 1, j - \delta + 1, 2 - \delta, n\pi^k \right),
\]
in which

\[
R(\varpi) = U_1(\varpi)P_1(\varpi) + U_2(\varpi)P_2(\varpi),
\]

where
\[
\frac{d\Omega^2 r^3 e^{-m(r/b)^k}}{\alpha_1(1 - n(r/b)^k)} = 0,
\]

Note that, the first derivative of the general hypergeometric function is given by:
\[
\frac{\partial\Omega^2 r^3 e^{-m(r/b)^k}}{\alpha_1(1 - n(r/b)^k)} = 0,
\]

where \( \partial_1 \) and \( \partial_2 \) are arbitrary integration constants and
\[
P_1(\varpi) = \pi^{1/2} M \left( i, j, \delta, n\pi^k \right),
\]
\[
P_2(\varpi) = \pi^{1/2} M \left( i - \delta + 1, j - \delta + 1, 2 - \delta, n\pi^k \right),
\]
in which

\[
R(\varpi) = U_1(\varpi)P_1(\varpi) + U_2(\varpi)P_2(\varpi),
\]

where
\[
\frac{d\Omega^2 r^3 e^{-m(r/b)^k}}{\alpha_1(1 - n(r/b)^k)} = 0,
\]

Note that, the first derivative of the general hypergeometric function is given by:
\[
\frac{\partial\Omega^2 r^3 e^{-m(r/b)^k}}{\alpha_1(1 - n(r/b)^k)} = 0,
\]

where \( \partial_1 \) and \( \partial_2 \) are arbitrary integration constants and
\[
P_1(\varpi) = \pi^{1/2} M \left( i, j, \delta, n\pi^k \right),
\]
\[
P_2(\varpi) = \pi^{1/2} M \left( i - \delta + 1, j - \delta + 1, 2 - \delta, n\pi^k \right),
\]
in which

\[
R(\varpi) = U_1(\varpi)P_1(\varpi) + U_2(\varpi)P_2(\varpi),
\]

where
\[
\frac{d\Omega^2 r^3 e^{-m(r/b)^k}}{\alpha_1(1 - n(r/b)^k)} = 0,
\]

Note that, the first derivative of the general hypergeometric function is given by:
\[
\frac{\partial\Omega^2 r^3 e^{-m(r/b)^k}}{\alpha_1(1 - n(r/b)^k)} = 0,
\]

where \( \partial_1 \) and \( \partial_2 \) are arbitrary integration constants and
\[
P_1(\varpi) = \pi^{1/2} M \left( i, j, \delta, n\pi^k \right),
\]
\[
P_2(\varpi) = \pi^{1/2} M \left( i - \delta + 1, j - \delta + 1, 2 - \delta, n\pi^k \right),
\]
in which

\[
R(\varpi) = U_1(\varpi)P_1(\varpi) + U_2(\varpi)P_2(\varpi),
\]

where
\[
\frac{d\Omega^2 r^3 e^{-m(r/b)^k}}{\alpha_1(1 - n(r/b)^k)} = 0,
\]
Consequently, the exact general solution for the radial displacement can be written as

\[ u(\phi) = r^{(\lambda + k)} M_1(\phi) \left[ C_1 + F_1(\phi) \right] + r^{(-\lambda)} M_2(\phi) \left[ C_2 - F_2(\phi) \right]. \]  

(20)

where

\[ C_1 = n^{(2 + \lambda + k)} \hat{C}_1, \quad C_2 = n^{(2 - \lambda + k)} \hat{C}_2, \]  

and

\[ \sigma_{rr}(\phi) = \frac{1 - n^2}{b} \left[ r^{(\lambda + k)} \left( C_1 + F_1(\phi) \right) + n^2 \left( \lambda \alpha_{11} + \alpha_{12} \right) \frac{dM_1}{d\phi} \right] \]

\[ + r^{(-\lambda)} \left( C_1 - F_1(\phi) \right) + n^2 \left( \lambda \alpha_{11} - \alpha_{12} \right) \frac{dM_2}{d\phi} \]  

(23)

\[ \sigma_{\theta\theta}(\phi) = \frac{1 - n^2}{b} \left[ r^{(\lambda + k)} \left( C_1 + F_1(\phi) \right) + n^2 \left( \lambda \alpha_{22} \right) \frac{dM_1}{d\phi} \right] \]

\[ + r^{(-\lambda)} \left( C_1 - F_1(\phi) \right) + n^2 \left( \lambda \alpha_{22} \right) \frac{dM_2}{d\phi} \]  

(24)

\[ \sigma_{zz}(\phi) = \frac{1 - n^2}{b} \left[ r^{(\lambda + k)} \left( C_1 + F_1(\phi) \right) + n^2 \left( \lambda \alpha_{33} \right) \frac{dM_1}{d\phi} \right] \]

\[ + r^{(-\lambda)} \left( C_1 - F_1(\phi) \right) + n^2 \left( \lambda \alpha_{33} \right) \frac{dM_2}{d\phi} \]  

(25)

Note that, if \( n = m = 0 \) then \( h(r) = h_0, c_{ij} = \alpha_{ij}, \rho = \rho_0 \) and the radial displacement given in Equation (20) for the rotating uniform thickness and density homogeneous orthotropic hollow cylinder is reduced to

\[ u(\phi) = C_1 r^{(\lambda + k)} + C_2 r^{(-\lambda)} + \frac{\rho_0 \Omega^2 b^2 \tau^2}{\alpha_1 (\lambda^2 - 9)} \]  

(26)

also, the corresponding stresses in this case are given by:

\[ \sigma_{rr}(\phi) = \frac{1}{b} \left[ C_1 (\lambda \alpha_{11} + \alpha_{12}) \tau^{(\lambda + k)} - C_2 (\lambda \alpha_{11} - \alpha_{12}) \tau^{(-\lambda - k)} \right] + \frac{3 \alpha_{11} + \alpha_{12}}{\alpha_1 (\lambda^2 - 9)} \rho_0 \Omega^2 b^2 \tau^2, \]

\[ \sigma_{\theta\theta}(\phi) = \frac{1}{b} \left[ C_1 (\lambda \alpha_{22}) \tau^{(\lambda + k)} - C_2 (\lambda \alpha_{22}) \tau^{(-\lambda - k)} \right] + \frac{3 \alpha_{22}}{\alpha_1 (\lambda^2 - 9)} \rho_0 \Omega^2 b^2 \tau^2, \]

\[ \sigma_{zz}(\phi) = \frac{1}{b} \left[ C_1 (\lambda \alpha_{33}) \tau^{(\lambda + k)} - C_2 (\lambda \alpha_{33}) \tau^{(-\lambda - k)} \right] + \frac{3 \alpha_{33}}{\alpha_1 (\lambda^2 - 9)} \rho_0 \Omega^2 b^2 \tau^2. \]

(27)

In addition, for isotropic cylinder we have \[ \alpha_{11} = \alpha_{22} = \frac{E(1 - \nu)}{(1 + \nu)(1 - 2\nu)}, \quad \alpha_{12} = \alpha_{13} = \alpha_{23} = \frac{E\nu}{(1 + \nu)(1 - 2\nu)}. \]  

(28)

where \( E \) and \( \nu \) are Young's modulus and Poisson's ratio of the cylinder material. Using Equation (28) we find that the solution given in Equations (26) and (27) for the rotating uniform thickness and density homogeneous isotropic hollow cylinder takes the form:

\[ u(\phi) = C_1 \tau^{(\lambda + k)} + C_2 \tau^{(-\lambda - k)} + \frac{\rho_0 \Omega^2 b^2 \tau^2}{8E(1 - \nu)} \]

\[ \sigma_{rr}(\phi) = \frac{E}{b(1 + \nu)(1 - 2\nu)} \left[ C_1 - C_2 \right] + \frac{3 - 2\nu}{8(1 - \nu)} \rho_0 \Omega^2 b^2 \tau^2, \]

\[ \sigma_{\theta\theta}(\phi) = \frac{E}{b(1 + \nu)(1 - 2\nu)} \left[ C_1 - C_2 \right] + \frac{(1 + 2\nu)}{8(1 - \nu)} \rho_0 \Omega^2 b^2 \tau^2, \]

\[ \sigma_{zz}(\phi) = \frac{2Ev}{b(1 + \nu)(1 - 2\nu)} \left[ C_1 - \frac{(1 + \nu)(1 - 2\nu)}{4E(1 - \nu)} \rho_0 \Omega^2 b^2 \tau^2 \right]. \]

(29)
The previous elastic solutions will be completed by calculating the integration constants \( C \) using various boundary conditions on the surfaces of the hollow cylinder.

### 4. Rotation of Elastic Hollow Cylinders

In the present section, we will obtain the elastic solutions for the rotating hollow cylinder. For the present hollow cylinder, the solution requires that one boundary condition be satisfied at each surface. The radial stress must be vanished at the free surface (F) of the cylinder while the radial displacement must be equal to zero at the clamped surface (C) of the cylinder.

#### 4.1. Free-Free (FF) Hollow Cylinder

When the inner and outer surfaces \( (r = a, r = b) \) or \( \bar{r} = a / b = \bar{a}, \bar{r} = 1 \) of the cylinder are free of any traction, the boundary conditions are given by:

\[
\begin{align*}
\sigma_r(\bar{r}) &= 0 \quad \text{at} \quad \bar{r} = \bar{a}, \\
\sigma_r(\bar{r}) &= 0 \quad \text{at} \quad \bar{r} = 1.
\end{align*}
\]

Using the above conditions into Equation (23), the constants \( C_1 \) and \( C_2 \) are given by

\[
C_1 = \frac{F_1(1)S_{21} - F_2(1)S_{22} + S_{23}S_{12} - [F_1(\bar{\sigma})S_{11} - F_2(\bar{\sigma})S_{12} + S_{13}]S_{22}}{S_1S_{22} - S_{12}S_{21}},
\]

\[
C_2 = \frac{F_1(\bar{\sigma})S_{11} - F_2(\bar{\sigma})S_{12} + S_{13}S_{22} - [F_1(1)S_{21} - F_2(1)S_{22} + S_{23}]S_{11}}{S_1S_{22} - S_{12}S_{21}},
\]

where

\[
\begin{align*}
S_{11} &= \bar{\sigma}^{(\alpha)} \left[ \alpha_1 M_1(\bar{\sigma}) + (\lambda \alpha_1 + \alpha_2) \frac{M_3(\bar{\sigma})}{\bar{\sigma}} \right] \\
S_{12} &= \bar{\sigma}^{(\beta)} \left[ \alpha_1 M_2(\bar{\sigma}) - (\lambda \alpha_1 + \alpha_2) \frac{M_3(\bar{\sigma})}{\bar{\sigma}} \right] \\
S_{13} &= \alpha_1 \left[ \bar{\sigma}^{(\gamma)} M_1(\bar{\sigma}) + \bar{\sigma}^{(\rho)} M_3(\bar{\sigma}) \right] F_1(\bar{\sigma}) - \bar{\sigma}^{(\rho)} M_2(\bar{\sigma}) F_2(\bar{\sigma}) \\
S_{21} &= \alpha_1 M_1(1) + (\lambda \alpha_1 + \alpha_2) M_1(1) \\
S_{22} &= \alpha_1 M_2(1) - (\lambda \alpha_1 - \alpha_2) M_2(1) \\
S_{23} &= \alpha_1 \left[ M_2(1) - \bar{\sigma}^{(\rho)} M_3(\bar{\sigma}) \right] F_1(1) - \alpha_2 M_3(1) F_2(1)
\end{align*}
\]

in which the prime (') means differentiation with respect to \( \bar{r} \).

The radial displacement and stresses for the rotating variable thickness and density inhomogeneous orthotropic hollow cylinder with free surfaces can be calculated from Equations (20), (23)-(25) and (32).

The solution given in Equations (26) and (27) for the rotating uniform thickness and density homogeneous orthotropic hollow cylinder with free surfaces can be obtained with the help of the following constants:

\[
\begin{align*}
C_1 &= \frac{(3 \alpha_1 + \alpha_2) \bar{\sigma}^{(\rho)-1} - 1}{\alpha_1 \left( \lambda^2 - 9 \right) \left( \lambda \alpha_1 + \alpha_2 \right) \bar{\sigma}^{(\rho)-1} - \bar{\sigma}^{(\rho)-1}}, \\
C_2 &= \frac{(3 \alpha_1 + \alpha_2) \bar{\sigma}^{(\rho)-1} - 1}{\alpha_1 \left( \lambda^2 - 9 \right) \left( \lambda \alpha_1 + \alpha_2 \right) \bar{\sigma}^{(\rho)-1} - \bar{\sigma}^{(\rho)-1}}
\end{align*}
\]

Also, the radial displacement and stresses given in Equation (29) for the rotating uniform thickness and density homogeneous isotropic hollow cylinder with free surfaces can be written as

\[
\begin{align*}
u(\bar{r}) &= \frac{(1 + \nu)(1 - 2\nu)}{8E(1 - \nu)} \left[ (1 + \bar{\sigma}^2)(3 - 2\nu) + \frac{3 - 2\nu}{1 + 2\nu} \frac{\bar{\sigma}^2}{\bar{r}^2 - \bar{r}^2} \right] \rho \Omega^2 b^3 \\
\sigma_r(\bar{r}) &= \frac{3 - 2\nu}{8(1 - \nu)} \left[ 1 + \bar{\sigma}^2 - \frac{\bar{\sigma}^2}{\bar{r}^2 - \bar{r}^2} \right] \rho \Omega^2 b^3 \\
\sigma_{\theta r}(\bar{r}) &= \frac{3 - 2\nu}{8(1 - \nu)} \left[ 1 + \bar{\sigma}^2 - \frac{3 - 2\nu}{1 + 2\nu} \bar{\sigma}^2 \right] \rho \Omega^2 b^3 \\
\sigma_{r\theta}(\bar{r}) &= \frac{\nu}{4(1 - \nu)} \left[ (1 + \bar{\sigma}^2)(3 - 2\nu - 2\bar{\sigma}^2) \right] \rho \Omega^2 b^3
\end{align*}
\]
This is the well-known solution of the rotating uniform thickness cylinder [19].

4.2. Clamped-Clamped (CC) Hollow Cylinder

When the inner and outer surfaces \((\varpi = \varpi_s, \varpi = 1)\) of the cylinder are clamped, the boundary conditions are given by:

\[
\begin{align*}
\sigma_{rr}(\varpi = 0) &= 0, \\
\sigma_{tt}(\varpi = 1) &= 0.
\end{align*}
\]

From these conditions and Equation (20), the constants \(C_1\) and \(C_2\) are given by

\[
\begin{align*}
C_1 &= \frac{\left[M_1(1)F_1(1) - M_2(1)F_2(1)\right]S_{14} - \left[F_1(\varpi)S_{14} - F_2(\varpi)S_{14}\right]M_2(1)}{M_2(1)S_{14} - M_1(1)S_{14}}, \\
C_2 &= \frac{F_1(\varpi)S_{14} - F_2(\varpi)S_{14}}{M_2(1)S_{14} - M_1(1)S_{14}}.
\end{align*}
\]

where

\[
S_{14} = \bar{\pi}^{(+)}M_1(\bar{\varpi}), \quad S_{41} = \bar{\pi}^{(-)}M_2(\bar{\varpi}).
\]

With the help of Equations (20), (23)-(25) and (36), we can obtain the radial displacement and stresses for the rotating variable thickness and density inhomogeneous orthotropic hollow cylinder with clamped surfaces.

The solution given in Equation (27) for the rotating uniform thickness and density homogeneous orthotropic hollow cylinder with clamped surfaces can be calculated by:

\[
\begin{align*}
\sigma_{rr}(\varpi = 0) &= 0, \quad u(\varpi = \varpi_s), \\
\sigma_{tt}(\varpi = 1) &= 0, \quad u(\varpi = 1).
\end{align*}
\]

Finally, the radial displacement and stresses given in Equation (29) for the rotating uniform thickness and density homogeneous isotropic hollow cylinder with clamped surfaces becomes

\[
\begin{align*}
\sigma_{rr}(\varpi = 0) &= 0, \quad u(\varpi = \varpi_s), \\
\sigma_{tt}(\varpi = 1) &= 0, \quad u(\varpi = 1).
\end{align*}
\]

4.3. Free-Clamped (FC) Hollow Cylinder

When the inner surface of the cylinder \(C_1(\varpi = \varpi_s)\) is free of any traction and the outer surface \(\varpi = 1\) is clamped, the boundary conditions are given by:

\[
\begin{align*}
\sigma_{rr}(\varpi = 0) &= 0, \quad u(\varpi = \varpi_s), \\
\sigma_{tt}(\varpi = 1) &= 0, \quad u(\varpi = 1).
\end{align*}
\]

From Equations (40), (20) and (23), the constants \(C_1\) and \(C_2\) are given by

\[
\begin{align*}
C_1 &= \frac{\left[M_1(1)F_1(1) - M_2(1)F_2(1)\right]S_{12} - \left[F_1(\varpi)S_{12} - F_2(\varpi)S_{12} + S_{14}\right]M_2(1)}{M_2(1)S_{12} - M_1(1)S_{12}}, \\
C_2 &= \frac{F_1(\varpi)S_{12} - F_2(\varpi)S_{12} + S_{14}}{M_2(1)S_{12} - M_1(1)S_{12}}.
\end{align*}
\]

Substituting from these constants into Equations (20), (23)-(25), we can get the radial displacement and stresses for the rotating variable thickness and density inhomogeneous orthotropic hollow cylinder with free inner and clamped outer surfaces.

In addition, the solution for the rotating uniform thickness and density homogeneous orthotropic hollow cylinder with free inner and clamped outer surfaces can be obtained from Equations (26) and (27) with the help of the following constants:
\[ C_1 = \frac{1}{\alpha_1(\lambda^2 - 9)} \left[ (\lambda_1 + \alpha_2) \bar{a}^{(3-\lambda)} + (\lambda_1 - \alpha_2) \bar{a}^{(3-\lambda)} \right] \bar{a}^2 \rho \Omega^2 b^3 \]
\[ C_2 = \frac{1}{\alpha_1(\lambda^2 - 9)} \left[ (\lambda_1 + \alpha_2) \bar{a}^{(3-\lambda)} - (\lambda_1 - \alpha_2) \bar{a}^{(3-\lambda)} \right] \bar{a}^2 \rho \Omega^2 b^3 \]  

Equation (42)

Also, the radial displacement and stresses given in Equation (29) for the rotating uniform thickness and density homogeneous isotropic hollow cylinder with free inner and clamped outer surfaces can be obtained in the following form:

\[ u(\bar{r}) = \frac{(1 + \nu)(1 - 2\nu)}{8E(1 - \nu)} \left[ \frac{1 - 2\nu + \bar{a}^2 (3 - 2\nu)}{1 - 2\nu + \bar{a}^2} \right] \rho \Omega^2 b^3 \bar{\nu}, \]
\[ \sigma_{rr}(\bar{r}) = \frac{\rho \Omega^2 b^2}{8(1 - \nu)} \left[ \frac{1 - 2\nu + \bar{a}^2 (3 - 2\nu)}{1 - 2\nu + \bar{a}^2} \right] \bar{a}^2 \rho \Omega^2 b^3 \]
\[ \sigma_{\theta\theta}(\bar{r}) = \frac{\rho \Omega^2 b^2}{8(1 - \nu)} \left[ \frac{1 - 2\nu + \bar{a}^2 (3 - 2\nu)}{1 - 2\nu + \bar{a}^2} \right] \bar{a}^2 \rho \Omega^2 b^3 \]
\[ \sigma_{zz}(\bar{r}) = \frac{\nu}{4(1 - \nu)} \left[ \frac{1 - 2\nu + \bar{a}^2 (3 - 2\nu)}{1 - 2\nu + \bar{a}^2} \right] - 2\bar{r}^2 \rho \Omega^2 b^3. \]  

4.4. Clamped-Free (CF) Hollow Cylinder

When the inner surface of the cylinder (\( \bar{r} = \bar{r}_i \)) is clamped and the outer surface (\( \bar{r} = \bar{r}_o \)) is free of any traction, the boundary conditions are given by:

\[ C_1 = \frac{[F_1(i)S_{21} - F_2(i)S_{22} + S_{23}]S_{44} - [F_1(\bar{r})S_{44} - F_2(\bar{r})S_{44}]S_{22}}{S_{22}S_{44} - S_{23}S_{44}}, \]
\[ C_2 = \frac{[F_1(\bar{r})S_{44} - F_2(\bar{r})S_{44}]S_{21} - [F_1(1)S_{21} - F_2(1)S_{21} + S_{23}]S_{44}}{S_{22}S_{44} - S_{23}S_{44}}. \]  

Equation (45)

The radial displacement and stresses for the rotating variable thickness and density inhomogeneous orthotropic hollow cylinder with clamped inner and free outer surfaces can be obtained from Equations (20), (23)-(25) and (45).

Also, the solution given in Equation (27) for the rotating uniform thickness and density homogeneous orthotropic hollow cylinder with clamped inner and free outer surfaces can be calculated with the help of the following constants:

\[ C_1 = \frac{1}{\alpha_1(\lambda^2 - 9)} \left[ (\lambda_1 + \alpha_2) \bar{a}^{(3-\lambda)} + (\lambda_1 - \alpha_2) \bar{a}^{(3-\lambda)} \right] \bar{a}^2 \rho \Omega^2 b^3 \]
\[ C_2 = \frac{1}{\alpha_1(\lambda^2 - 9)} \left[ (\lambda_1 + \alpha_2) \bar{a}^{(3-\lambda)} - (\lambda_1 - \alpha_2) \bar{a}^{(3-\lambda)} \right] \bar{a}^2 \rho \Omega^2 b^3 \]  

Equation (46)

Finally, one can obtain easily the radial displacement and stresses given in Equation (29) for the rotating uniform thickness and density homogeneous isotropic hollow cylinder with clamped inner and free outer surfaces in the following form:

\[ u(\bar{r}) = \frac{(1 + \nu)(1 - 2\nu)}{8E(1 - \nu)} \left[ \frac{3 - 2\nu + \bar{a}^2 (1 - 2\nu)}{1 - 2\nu + \bar{a}^2} - \frac{3 - 2\nu - \bar{a}^2 (1 - 2\nu)}{1 - 2\nu + \bar{a}^2} \right] \rho \Omega^2 b^3 \bar{\nu}, \]
\[ \sigma_{rr}(\bar{r}) = \frac{\rho \Omega^2 b^2}{8(1 - \nu)} \left[ \frac{3 - 2\nu + \bar{a}^2 (1 - 2\nu)}{1 - 2\nu + \bar{a}^2} - \frac{3 - 2\nu - \bar{a}^2 (1 - 2\nu)}{1 - 2\nu + \bar{a}^2} \right] \bar{a}^2 \rho \Omega^2 b^3 \]
\[ \sigma_{\theta\theta}(\bar{r}) = \frac{\rho \Omega^2 b^2}{8(1 - \nu)} \left[ \frac{3 - 2\nu + \bar{a}^2 (1 - 2\nu)}{1 - 2\nu + \bar{a}^2} - \frac{3 - 2\nu - \bar{a}^2 (1 - 2\nu)}{1 - 2\nu + \bar{a}^2} \right] \bar{a}^2 \rho \Omega^2 b^3 \]
\[ \sigma_{zz}(\bar{r}) = \frac{\nu}{4(1 - \nu)} \left[ \frac{3 - 2\nu + \bar{a}^2 (1 - 2\nu)}{1 - 2\nu + \bar{a}^2} - \frac{3 - 2\nu - \bar{a}^2 (1 - 2\nu)}{1 - 2\nu + \bar{a}^2} \right] \bar{a}^2 \rho \Omega^2 b^3. \]  

Equation (47)
5. Conclusions

The rotation problem of a variable-thickness inhomogeneous, orthotropic, hollow cylinder has been studied. Analytical solution for rotating variable-thickness, inhomogeneous, orthotropic, hollow cylinder subjected to different boundary conditions are derived. The displacement and stresses for rotating uniform-thickness, homogeneous, isotropic, hollow cylinder are obtained as special cases of the investigated problem. In the second part of this paper we will present the corresponding viscoelastic solutions and some applications concerning the effects due to many parameters on the radial displacement and stresses.
