ABSTRACT
In this paper, the existence and uniqueness of solution systems for some binary nonlinear operator equations are discussed by using cone and partial order theory and monotone iteration theory, and the iterative sequences which converge to solution of operator equations and error estimates for iterative sequences are also given. Some corresponding results are improved and generalized. Finally, the applications of our results are given.

Keywords: Cone and Partial Order; Solution; Nonlinear Binary Operator; Operator Equations

1. Introduction
In recent years, more and more scholars have studied binary operator equations and have obtained many conclusions, such as references [1-3] etc. In this paper, we will discuss solutions for ordinal symmetric contraction operator and obtain some general conclusions; some corresponding results of references [4,5] are improved and generalized. Finally, we apply our conclusions to two point boundary value problems with two degree superlinear ordinary differential equations.

In the following, let $E$ always be a real Banach space which is partially ordered by a cone $P$, $P$ be normal cone of $E$, $N$ is normal constant of $P$, partial order $\leq$ is determined by $P$, $\theta$ denotes zero element of $E$. For $u, v \in E$ and $u < v$, let

$$D = [u, v] = \{ x \in E : u \leq x \leq v \}$$

denotes an ordering interval of $E$.

The concepts of normal cone and partially order, mixed monotone operator, coupled solutions of operator equations etc. see [6].

Definition 1.1. Let $A : D \times D \rightarrow E$ be binary operator, $A$ is said to be $L$-ordering symmetric contraction operator if there exists a bounded linear operator $L : E \rightarrow E$, which its spectral radius $r(L) < 1$ such that

$$A(y, x) - A(x, y) \leq L(y - x)$$

for any $x, y \in D, x \leq y$, where $L$ is called contraction operator of $A$.

2. Main Results
Theorem 2.1. Let $A : D \times D \rightarrow E$ be $L$-ordering symmetric contraction operator, and there exists a $\alpha \in [0, 1)$, for any $u \leq x \leq x_1 \leq v, \ u \leq y_1 \leq y \leq v$ such that

$$A(x_1, y_1) - A(x_1, y_1) \geq -\alpha (x_1 - y_1). \quad (1)$$

If condition

$$u \leq A(u, v), \ A(v, u) \leq v - \alpha (v - u);$$

or

$$u + \alpha (v - u) \leq A(u, v), \ A(v, u) \leq v$$

holds, then the following statements hold:

(C1) $A(x, x) = x$ has a unique solution $x^* \in D$, and for any coupled solution $x, y \in D$ such that $x = y = x^*$;

(C2) For any $x_0, y_0 \in D$, we make up symmetric iterative sequences

$$x_n = (\alpha + 1)^{-1} \left( A(x_{n-1}, y_{n-1}) + \alpha x_{n-1} \right),$$

$$y_n = (\alpha + 1)^{-1} \left( A(y_{n-1}, x_{n-1}) + \alpha y_{n-1} \right),$$

for $n = 1, 2, 3, \ldots$,

then

$$x_n \rightarrow x^*, \ y_n \rightarrow x^* \ (n \rightarrow \infty),$$

and for any $\beta \in (r(L), 1)$, there exists a natural numbers $m$, if $n \geq m$, we get error estimates for iterative sequences (2):

$$\left\| x_n(y_n) - x^* \right\| \leq 2N \left( \frac{\alpha + \beta}{\alpha + 1} \right)^m \| v - v \| ;$$

Copyright © 2013 SciRes.
Proof. Set

\[ B(x,y) = \frac{1}{\alpha + 1} \left[ A(x,y) + \alpha x \right], \]

if condition (H1) or (H2) holds, then it is obvious

\[ u \leq B(u,v), B(v,u) \leq v, \]

by (1), we easily prove that \( B : D \times D \rightarrow E \) is mixed monotone operator, and for any \( u \leq x \leq y \leq v \) such that

\[ \theta \leq B(y,x) - B(x,y) \leq H(y - x), \]

where

\[ H = (\alpha + 1)^{-1} (I + \alpha I) \]

is a bounded linear operator, \( I \) is identical operator.

By the mathematical induction, we easily prove that

\[ \theta \leq B^\varepsilon (y,x) - B^\varepsilon (x,y) \leq H^\varepsilon (y - x), \]

where

\[ B^\varepsilon (x,y) = B(B^{\varepsilon - 1} (x,y), B^{\varepsilon - 1} (x,y)) , x,y \in D, n \geq 2. \]

By the character of normal cone \( P \), we implies

\[ \|B^n (y,x) - B^n (x,y)\| \leq N \|H^n \| \|y - x\| , \]

for any \( \beta \in (r(L),1) \), since

\[ \lim_{n \to \infty} \|H^n \| = r(H) \leq \frac{\alpha + r(L)}{\alpha + 1} < \frac{\alpha + \beta}{\alpha + 1} < 1, \]

so there exists a natural numbers \( m \), if \( n \geq m \), such that

\[ \|H^n \| < \left( \frac{\alpha + \beta}{\alpha + 1} \right)^m \]

and constant \( N \|H^n \| < 1. \)

Considering mixed monotone operator \( B^n \) and constant \( N \|H^n \| \), by Theorem 3 in reference [3], then we know \( B^n (x,x) = x \) has an unique solution \( x* \), and for any coupled solution \( x,y \in D \) such that

\[ x = y = x*. \]

From

\[ B^n \left( B\left( x^*, x^* \right), B\left( x^*, x^* \right) \right) \]

\[ = B \left( B^n \left( x^*, x^* \right), B^n \left( x^*, x^* \right) \right) = B \left( x^*, x^* \right) \]

and uniqueness of solutions with \( B^n (x,x) = x \), then we have \( B \left( x^*, x^* \right) = x^* \) and \( A \left( x^*, x^* \right) = x^* \).

We take note of that \( A(x,x) = x \) and \( B(x,x) = x \) have same coupled solution, therefore coupled solution for \( B(x,x) = x \) must be coupled solution for \( A(x,x) = x \), consequently, (C1) has been proved.

Considering that iterative sequence (2) and set iterative sequences:

\[ u_n = B(u_{n-1}, v_{n-1}), v_n = B(v_{n-1}, u_{n-1}), \]

where \( u_0 = u_0 = v_0 = v \), it is obvious that

\[ x_n = B(x_{n-1}, y_{n-1}), y_n = B(y_{n-1}, x_{n-1}), \]

\[ \theta \leq v_n - x_n \leq H^n (v - u), \]

by the mathematical induction and character of mixed monotone of \( B \), then

\[ u_n \leq x^* \leq v_n, u_n \leq x_n \leq v_n, u_n \leq y_n \leq v_n, \]

hence

\[ \|v_n - u_n\| \leq N \|v_n - u_n\|, \]

\[ \|x^* - u_n\| \leq N \|v_n - u_n\|, \]

moreover, if \( n \geq m \), we get

\[ \|v_n - u_n\| \leq 2N \|v_n - u_n\| \leq 2N \|H^n \| |u - v| \]

consequently, \( x_n \to x^*, v_n \to x^* (n \to \infty) \).

Remark 1. When \( \alpha = 0 \), Theorem 1 in [4] is a special case of this paper, Theorem 2.1 under condition (H1) or (H2).

Corollary 2.1. Let \( A : D \times D \rightarrow E \) be \( L \)-ordering symmetric contraction operator, if there exists a \( \alpha \in [0,1] \) such that \( A \) satisfies condition of Theorem 2.1, then (C1), (C2) hold and the following statements holds:

(C3) For any \( \beta \in (r(L),1) \) and \( \alpha + \beta < 1 \), we make up iterative sequences

\[ u_n = A(u_{n-1}, v_{n-1}), \]

\[ v_n = A(v_{n-1}, u_{n-1}) + \alpha (v_{n-1} - u_{n-1}), \]

\[ n = 1, 2, 3, \ldots \] \hspace{1cm} (3)

or

\[ u_n = A(u_{n-1}, v_{n-1}) - \alpha (v_{n-1} - u_{n-1}), \]

\[ v_n = A(v_{n-1}, u_{n-1}), \]

\[ n = 1, 2, 3, \ldots \] \hspace{1cm} (4)

where \( u_0 = u \), \( v_0 = v \) thus \( u_n \to x^*, v_n \to x^* (n \to \infty) \), and there exists a natural numbers \( m \), if \( n \geq m \), we have error estimates for iterative sequences (3) or (4):

\[ \|v_n - x^*\| \leq N \left( \alpha + \beta \right)^m \|u - v\|. \] \hspace{1cm} (5)

Proof. By the character of mixed monotone of \( A \), then (1) and (C1), (C2) \{in (1), (C2) where \( \alpha = 0 \) hold\}. In the following, we will prove (C3).

Consider iterative sequence (3), since

\[ u \leq x^* \leq v, \]

so we get

\[ u_n = A(u,v) \leq A(x^*, x^*) \]

\[ = x^* \leq A(v,u) = v - \alpha (v - u) \leq v, \]
by the mathematical induction, we easily prove
\[ u_n \leq x' \leq v_n, \quad n \geq 1 \]
hence
\[ \theta \leq x' - u_n \leq v_n - u_n, \quad \theta \leq v_n - x' \leq v_n - u_n. \]
It is clear
\[ \theta \leq v_n - u_n \leq (L + \alpha I)(v_{n-1} - u_{n-1}) = (L + \alpha I)^n(v-u), \quad n \geq 1. \]
For any \( \beta \in (r(L), 1) \), \( \alpha + \beta < 1 \), since
\[
\lim_{n \to \infty} \left\| (L + \alpha I)^n \right\| = r(L + \alpha I) \leq r(L) + \alpha < \alpha + \beta < 1,
\]
thus there exists a natural numbers \( m \), if \( n \geq m \), such that
\[
\left\| (L + \alpha I)^n \right\| < (\alpha + \beta)^n.
\]
Moreover,
\[
\left\| u_n(v_n) - x' \right\| \leq N \left\| (L + \alpha I)^n \right\| \left\| v - v \right\|
\leq N (\alpha + \beta)^n \left\| v - v \right\|, \quad (n \geq m),
\]
consequently, \( u_n \to x' \), \( v_n \to x' \), \( (n \to \infty) \).
Similarly, we can prove (4).

**Theorem 2.2.** Let \( A : D \times D \to E \) be \( L \)-ordering symmetric contraction operator, if there exists a \( \alpha \in [0,1) \) such that
\[
(1-\alpha)u \leq A(u,v), \quad A(v,u) \leq (1-\alpha)v,
\]
then the following statements holds:
(C5) Operator equation
\[
A(x,x) = (1-\alpha)x
\]
has an unique solution \( x' \in D \), and for its any coupled solution \( x, y \in D \), such that \( x = y = x' \);
(C6) For any \( x_0, y_0, w_0, z_0 \in D \), we make up symmetric iterative sequence
\[
x_n = \frac{1}{1-\alpha} A(x_{n-1}, y_{n-1}), \quad y_n = \frac{1}{1-\alpha} A(y_{n-1}, x_{n-1}),
\]
\[ n = 1, 2, 3, \ldots, \]
\[
w_n = A(w_{n-1}, z_{n-1}) + \alpha w_{n-1}, \quad z_n = A(z_{n-1}, w_{n-1}) + \alpha z_{n-1},
\]
\[ n = 1, 2, 3, \ldots, \]
then
\[
x_n \to x', \quad y_n \to x', \quad w_n \to x', \quad z_n \to x' (n \to \infty),
\]
and that for any \( \beta \in (r(L), 1) \) and \( \alpha + \beta < 1 \), there exists a natural numbers \( m \), if \( n \geq m \), then we have error estimates for iterative sequences (6) and (7) respectively:
\[
\left\| x_n(y_n) - x' \right\| \leq 2N \left( \frac{\beta}{1-\alpha} \right)^n \left\| v - v \right\|.
\]
\[
\left\| w_n(z_n) - x' \right\| \leq 2N (\alpha + \beta)^n \left\| u - v \right\|.
\]
**Proof.** Set
\[
B(x,y) = \frac{1}{1-\alpha} A(x,y)
\]
or
\[
C(x,y) = A(x,y) + \alpha x,
\]
we can prove this theorem imitate proof of Theorem 2.1, over.
Similarly, we can prove following theorems.

**Theorem 2.3.** Let \( A : D \times D \to E \) be \( L \)-ordering symmetric contraction operator, if there exists a \( \alpha \in [0,1) \) such that
\[
u + \alpha v \leq A(u,v), \quad A(v,u) \leq v + \alpha u,
\]
then the following statements holds:
(C6) Equation
\[
A(x,x) = (1+\alpha)x
\]
has an unique solution \( x' \in D \), and for any coupled solution \( x, y \in D \) such that \( x = y = x' \);
(C7) For any \( x_0, y_0 \in D \), we make up symmetric iterative sequence
\[
x_n = \frac{1}{\alpha + 1} A(x_{n-1}, y_{n-1}), \quad y_n = \frac{1}{\alpha + 1} A(y_{n-1}, x_{n-1}),
\]
\[ n = 1, 2, 3, \ldots, \]
then that \( x_n \to x', \quad y_n \to x' (n \to \infty) \), moreover, \( \beta \in (r(L), 1) \), there exist natural number \( m \), if \( n \geq m \), then we have error estimates for iterative sequence (9):
Remark 2. When $\alpha = 0$, Corollary 2 in [4] is a special case of this paper Theorem 2.1 - 2.3.

Remark 3. The contraction constant of operator in [5] is expand into the contraction operator of this paper.

Remark 4. Operator $A$ of this paper does not need character of mixed monotone as operator in [6].

3. Application

We consider that two point boundary value problems for two degree super linear ordinary differential equations

$$
\begin{aligned}
&x^m + a(t)x^m + \frac{1}{1+b(t)}x = 0, \ t \in [0,1], \\
x(0) = x'(1) = 0. \ (m \geq 2).
\end{aligned}
$$

Let $k(t,s)$ be Green function with boundary value problem (7), that is

$$
\begin{aligned}
k(t,s) = \min \{t, s\} = \begin{cases} t, & t \leq s, \\ s, & s < t.
\end{cases}
\end{aligned}
$$

then that the solution with boundary value problem (7) and solution for nonlinear integral equation with type of Hammerstein

$$
x(t) = \int_0^t k(t,s) \left\{ a(s) \left[ x(s) \right]^m + \frac{1}{1+b(s)}x(s) \right\} ds,
$$

is equivalent, where

$$
\max_{t \in [0,1]} \int_0^t k(t,s) ds = \frac{1}{2}.
$$

Theorem 3.1. Let $a(t), b(t)$ are nonnegative continuous function in $[0,1]$,

$$
p = \max_{t \in [0,1]} a(t), \ q = \max_{t \in [0,1]} b(t).
$$

If $p < 1, mp + q < 2$, then boundary value problem (7) have an unique solution $x^*(t)$ such that

$$
0 \leq x^*(t) \leq 1, \ t \in [0,1];
$$

Moreover, for any initial function $x_0(t), y_0(t)$ such that

$$
0 \leq x_0(t) \leq 1, 0 \leq y_0(t) \leq 1, \ t \in [0,1],
$$

we make up iterative sequence

$$
\begin{aligned}
x_n(t) &= \int_0^t k(t,s) \left\{ a(s) \left[ x_{n-1}(s) \right]^m + \frac{1}{1+b(s)}y_{n-1}(s) \right\} ds, \\
y_n(t) &= \int_0^t k(t,s) \left\{ a(s) \left[ y_{n-1}(s) \right]^m + \frac{1}{1+b(s)}x_{n-1}(s) \right\} ds,
\end{aligned}
$$

$n = 1, 2, 3, \cdots$.

Then $x_n(t), y_n(t)$ uniform convergence to $x^*(t)$ on $[0,1]$, and we have error estimates

$$
\left| x_n(t) - x^*(t) \right| < 2 \left( \frac{mp+q}{2} \right)^n, \ t \in [0,1],\ n = 1, 2, 3, \cdots.
$$

Proof. Let $E = C[0,1], P = \{ x \in E \mid x(t) \geq 0, t \in [0,1] \}$.

$$
\| x \| = \max_{t \in [0,1]} |x(t)|
$$

denote norm of $E$, then that $E$ has become Banach space, $P$ is normal cone of $E$ and its normal constant $N = 1$. It is obvious that integral Equation (8) is transformed to operator equation $A(x,x) = x$, where

$$
A(x,y)(t) = \int_0^t k(t,s) \left\{ a(s) \left[ x(s) \right]^m + \frac{1}{1+b(s)}y(s) \right\} ds, \ t \in [0,1],
$$

Set

$$
u = u(t) = 0, v = v(t) = 1,
$$

then $D = [0,1]$ denote ordering interval of $E$, $A : D \times D \to E$ is mixed monotone operator, and

$$
0 \leq A(0,1), A(1,0) \leq \frac{1+p}{2} < 1.
$$

Set

$$
Lx(t) = \int_0^t k(s,t) \left[ ma(s) + b(s) \right] x(s) ds, \ t \in [0,1],
$$

then $L : E \to E$ is bounded linear operator, its spectral radius

$$
r(L) \leq \frac{mp+q}{2} < 1,
$$

and for any $x, y \in E$, $0 \leq x(t) \leq y(t) \leq 1$ such that

$$
0 \leq A(y,x)(t) - A(x,y)(t) \leq L(y-x)(t),
$$

that is, $A$ is $L$-ordering symmetric contraction operator, by Theorem 2.1 (where $\alpha = 0$), then Theorem 3.1 has be proved.
