Abstract

Two-dimensional thermomagnetic convection of magnetic fluid possessing internal spin and relaxation of magnetization with high thermal sensitivity is numerically analyzed under a non-uniform magnetic and thermal field, using a spectral difference scheme, magnetic fluid is assumed to be placed between concentric cylinders, an azimuthal magnetic field being produced by an electric current through the inner cylinder, which is an adiabatic wall, whereas a half of the outer cylinder is kept at a high constant temperature and the rest half is at a lower constant temperature. As a result, in case of $\nabla T \times \nabla |H| \neq 0$, thermomagnetic convection is found to be produced, the convection pattern depends on electric current distribution, depending on which multiple or single circulation is produced, thus, it shows that thermomagnetic convection pattern is controlled by changing relative direction of temperature gradient to that of a magnetic field.

Keywords

Magnetic Fluid, Thermomagnetic Convection

1. Introduction

A familiar example of thermal convection is buoyancy-induced convection, where a driving body force resides in a force of gravity, another example is established in a heated magnetic fluid subject to a magnetic body force, which depends on a thermodynamic constitutive equation. The enhancement of convective heat transfer in magnetic fluids could be applied in cooling current-carrying conductors, and transmission lines, especially in gravity-free space. Characteristics of thermomagnetic convection are investigated by many researchers, e.g. Finlayson (1970) [1], Polevikov & Fertman (1977) [2], Busse & Riahi (1982) [3], Stiles &

In this paper, two-dimensional thermomagnetic convection of magnetic fluid possessing internal spin and relaxation of magnetization with high thermal sensitivity is numerically analyzed under a non-uniform magnetic and thermal field, using a spectral finite difference schemes, and the thermomagnetic convection pattern of magnetic fluid within an annulus is numerical investigated with spatial distributions of magnetic field variations.

2. Analysis

2.1. Physical Model

Analyzed is Two-dimensional thermomagnetic convection followed by a steady-state natural convection of magnetic fluid as shown in Figure 1, where a conductive wire of radius $R_0$ with a direct current $I_0$ is placed in the center of an annular space filled with a magnetic fluid of magnetic permeability $\mu_0$. It is assumed that magnetic fluid is magnetized by a magnetic field $H$ due to an external magnetic field from a wire current and an induction magnetic field of the magnetic fluid, those magnetic fluid is assumed to be at rest up to time $t = 0$ with a uniform temperature $T_l$, and at $t > 0$ a half part of the outside circumference is assumed to be fixed at a high temperature ($T_h$), and the rest half part of the outside circumference at a low temperature ($T_l$).

The following assumption applies:

1) The radius of wire is much smaller than that of the inside circle ($R_0 \ll R_1$).
2) The effect of magnetic field is limited within the distance $50R_0$.
3) The magnetic permeability of magnetic fluid is equal to that of vacuum.
4) The magnetic fluid is incompressible fluid.

Figure 1. The analytical region.
2.2. Governing Equations of an Incompressible Magnetic Fluid

The equation of continuity is
\[ \nabla \cdot \mathbf{v} = 0, \quad (1) \]

The momentum equation neglecting gravity force is
\[ \rho \frac{D\mathbf{v}}{Dt} = -\mathbf{\nabla} p + \eta \nabla^2 \mathbf{v} + \nabla \cdot (\mathbf{BH}) + \frac{I}{t_s} \nabla \times (\mathbf{\Omega} - \mathbf{\omega}), \quad (2) \]

where \( t \) is time, \( \mathbf{v} \) velocity, \( \rho \): mass density of magnetic fluid, \( p \): pressure, \( \eta \): viscosity of magnetic fluid in absence of a magnetic field, \( I \): average inertia moments of particles per unit volume, \( t_s \): the relaxation time of internal spin rotation, \( \mathbf{H} \): magnetic field, \( \mathbf{B} \): magnetic induction, \( \mathbf{\Omega} \): internal spin rate, \( \mathbf{\omega} \): effective rate of rotation of a fluid element \( = (1/2) \nabla \times \mathbf{v} \).

The internal angular momentum equation is
\[ \frac{D\mathbf{\Omega}}{Dt} = \gamma I \nabla^2 \mathbf{\Omega} - \frac{I}{t_s} \mathbf{\Omega} - \frac{1}{t_s} (\mathbf{\Omega} - \mathbf{\omega}) + \mu_0 \mathbf{M} \times \mathbf{H}, \quad (3) \]

where \( \gamma \) is a dissipation coefficient of inertia spin moment, \( \mathbf{M} \): magnetization of the magnetic fluid. The magnetization relaxation equation, Shliomis (1974) [9], is
\[ \frac{DM}{Dt} = \mathbf{\Omega} \times \mathbf{M} - \frac{1}{t_s} (\mathbf{M} - \mathbf{M}_0), \quad (4) \]

where \( t_s \) is a relaxation time of the particle rotation by Brownian rotation motion, and \( \mathbf{M}_0 \) is the equilibrium magnetization of the magnetic fluid, and magnitude is given by
\[ |M_0|(|H|, T) = \phi M_s(T) L \left( \frac{\pi \mu_0 M_s(T) d^3 |H|}{6 kT} \right), \quad (5a) \]

where \( L(x) = \coth x - 1/x \) is a Langevin function, \( T \): temperature, \( k \): Boltzmann constant, \( d \): diameter of the particle, \( \phi \): volume fraction of ferromagnetic particles, \( M_s \): magnetic moment of a particle, if \( T \leq 0.8 T_c \) (\( T_c \): temperature of Curie point),
\[ M_s(T) \approx M_s(0) \left( 1 - \frac{kT}{n \mu_0 M_s H_M} \right), \quad (5b) \]

where \( M_s \) is Bohrmagneton, \( n \): number of spin per unit atom of ferromagnetic metal, \( H_M \): molecular field.

The energy equation can be derived by Cowley and Rosensweig [10] as
\[ \rho \mathcal{C}_m \frac{DT}{Dt} - \mu_0 \rho TK \left( \frac{D|H|}{Dt} \right) = k_1 \nabla^2 T + \Phi, \quad (6) \]

where \( \mathcal{C}_m \) is the heat capacity at constant volume with a magnetic field, \( K \): pyromagnetic coefficient of magnetic fluid, \( k_1 \): thermal conductivity, \( \Phi \): a viscous dissipation term usually negligible. The Maxwell’s equation for a non-conducting fluid with no displacement current becomes
\[ \nabla \times \mathbf{H} = 0, \quad \nabla \cdot \mathbf{B} = 0, \quad (7) \]
\[ B = \mu_0 (H + M) \] \hspace{1cm} (8)

### 2.3. Coordinate System

Cartesian coordinate \((x, y)\) is fixed in the center of an annular pipe, the \(y\)-axis being vertically upward, Relationship between cylindrical and Cartesian coordinates is

\[ x + iy = Re^{i\theta} \] \hspace{1cm} (9)

where, a spectral finite difference method is applied for solving Equation (1) - Equation (8), and primary variables are expressed in a Fourier series to the circumferential \(\theta\)-direction.

### 2.4. Equation of the Distribution of Magnetic Field

Introduced are a magnetic induction stream functions, \(\psi_i^m\):

\[ B_\alpha = \frac{\partial \psi_i^m}{\partial y}, \quad B_\beta = -\frac{\partial \psi_i^m}{\partial x}, \] \hspace{1cm} (10)

\[ \psi_i^m = \psi_i^m - \frac{\mu_i I_i}{2\pi} \ln R, \] \hspace{1cm} (11)

where \(i = 1, 2, 3\) correspond to the following three regions:

- \(R_0 \leq R \leq R_1\):
  \[ \nabla^2 \psi_i^m = 0, \] \hspace{1cm} (12a)

- \(R_1 \leq R \leq R_2\):
  \[ \frac{1}{\mu_0} \nabla^2 \psi_i^m + \left( \frac{M_\theta}{R} + \frac{\partial M_\theta}{\partial R} - \frac{1}{R} \frac{\partial M_R}{\partial \theta} \right) = 0, \] \hspace{1cm} (12b)

- \(R_2 \leq R \leq 50R_2\):
  \[ \nabla^2 \psi_i^m = 0. \] \hspace{1cm} (12c)

where \(M_R\) and \(M_\theta\) are \(R\)- and \(\theta\)-component of magnetization of the magnetic fluid, \(M\).

### 2.5. Boundary Conditions

The boundary conditions used are as follows:

- At \(R = R_1\), no-slip, no-spin, and thermal insulation:
  \[ \left[ v \right]_{R=R_1} = 0, \quad \left[ \Omega \right]_{R=R_1} = 0, \quad \left( \frac{\partial T}{\partial R} \right)_{R=R_1} = 0, \] \hspace{1cm} (13)

- At \(R=R_2\), no-slip, no-spin, and Dirichlet temperature condition:
  \[ \left[ v \right]_{R=R_2} = 0, \quad \left[ \Omega \right]_{R=R_2} = 0, \] \hspace{1cm} (14)

  \[ T(\theta, R_2) = T_a \quad \text{for } \theta \in \left[ \frac{\pi}{2}, \frac{3\pi}{2} \right], \] \hspace{1cm} (15a)

  \[ T(\theta, R_2) = T_i \quad \text{for } \theta \in \left[ 0, \frac{\pi}{2} \right] \cup \left[ \frac{3\pi}{2}, 2\pi \right]. \] \hspace{1cm} (15b)
The normal component of the magnetic induction and the tangential component of the magnetic field are continuous across the interface between dissimilar regions,

\begin{align}
\text{at } R = R_1: [B_n]_n &= [B_n]_t, \quad [H_n]_n = [H_n]_t, \\
\text{at } R = R_2: [B_n]_n &= [B_n]_t, \quad [H_n]_n = [H_n]_t,
\end{align}

(16a)  

(16b)

where the subscript \( n \) and \( t \) denote normal and tangential component. Then the boundary condition of Equations 12(a)-(c) are given by

\begin{align}
\bar{\phi}_1^n &= 0, \quad \frac{\partial \phi_1^n}{\partial R} = 0 \quad (R = 0), \\
\frac{\partial \phi_2^n}{\partial R} &= \frac{\partial \phi_1^n}{\partial R} + \mu_0 M_\theta \quad (R = R_1), \\
\frac{\partial \phi_2^n}{\partial R} &= \frac{\partial \phi_1^n}{\partial R} + \mu_0 M_\theta \quad (R = R_2), \\
\bar{\phi}_2^n &= 0 \quad (R = 50R_2).
\end{align}

(17a)  

(17b)  

(17c)  

(17d)

### 3. Results

Assuming that the magnetic particle of magnetic fluid is iron oxide, and that the carrier liquid is hydrocarbon, the following constants and parameters of magnetic fluid are used

\begin{align}
C_m &= 2.09 \times 10^3 \text{ J} \cdot \text{K}^{-1} \cdot \text{kg}^{-1}, \quad d = 1.0 \times 10^{-8} \text{ m}, \quad H_M = 1.7 \times 10^9 \text{ A} \cdot \text{m}^{-1}, \\
I &= 1.0 \times 10^{-4} \text{ kg} \cdot \text{m}^{-1}, \quad k = 1.38 \times 10^{-23} \text{ J} \cdot \text{K}^{-1}, \quad k_i = 0.22 \text{ J} \cdot \text{K}^{-1} \cdot \text{m}^{-1} \cdot \text{s}^{-1}, \\
K &= 220 \text{ A} \cdot \text{m}^{-1} \cdot \text{K}^{-1}, \quad M_B = 1.17 \times 10^{-29} \text{ A} \cdot \text{m}^{-1}, \quad M_s(0) = 3.18 \times 10^{14} \text{ A} \cdot \text{m}^{-1}, \\
n &= 2.2, \quad \phi = 0.041, \quad \eta = 0.2 \text{ Pa} \cdot \text{s}, \quad t_s = 7.6 \times 10^{-7} \text{ s}, \quad t_i = 4.17 \times 10^{-11} \text{ s}, \\
\mu_0 &= 4\pi \times 10^{-7} \text{ H} \cdot \text{m}^{-1}, \quad \rho = 1.22 \times 10^3 \text{ kg} \cdot \text{m}^{-3}.
\end{align}

#### 3.1. Magnetic Body Force of Magnetic Fluid

Since the relaxation time \( t_s (~10^{-11} \text{ s}) \) of internal spin rotation and the dissipation coefficient \( \gamma (~ \approx t_s/2 \times 10^{-7} \text{ s}^{-1}) \) of inertia spin moment is very small, Equation (3) can be reduced as

\begin{align}
\frac{I}{t_s}(\Omega - \omega) = \mu_0 M \times H,
\end{align}

(18)

and substituting Equation (18) into Equation (2) leads to an approximate momentum equation:

\begin{align}
\rho \frac{Dv}{Dt} = -\nabla p + \eta \nabla^2 v + \mu_0 (M \cdot \nabla) H,
\end{align}

(19)

and then the curl of the magnetic body force is given by

\begin{align}
\nabla \times \mu_0 (M \cdot \nabla) H = \mu_0 \frac{\partial}{\partial t} \left[ \nabla T \times (H \cdot \nabla) H \right],
\end{align}

(20)

where \( \chi (= \chi(T, |H|)) \) is the magnetic susceptibility of magnetic fluid, and the magnetization of the magnetic fluid can be written as \( \mathbf{M} = \chi \mathbf{H} \). As for the Equation (20), the producing condition of thermomagnetic convection is derived in the gravity-free space as \( \nabla T \times \nabla |H| \neq 0 \).
3.2. Numerical Results

In the case of \( I_0 = 10 \, \text{A} \), \( T_0 - T_1 = 20 \, \text{K} \) and \( R_1/R_2 = 0.2 \), the isotherms, streamlines and dimensionless magnetization field strengths with the position of electric current wire varies are displayed as shown in Figures 2-4, where all quantities are made dimensionless base on a length \( L_0 (=R_2) \), a temperature \( T_0 (=T_h - T_l) \), and reference velocity \( V_0 (=H_0\sqrt{\mu_0/\rho}) \), \( H_0 (=L_0/2\pi L_0) \) is representative magnetic field. It shows that the convection pattern depends on electric current distribution, depending on which multiple or single circulation is produced. Thus, it is found that thermomagnetic convection is controlled by changing relative direction of temperature gradient to that of a magnetic field.

4. Conclusions

1) For producing thermomagnetic convection of a magnetic fluid, a spatially non-uniform of temperature and a spatially non-uniform of external magnetic field are required so that \( \nabla T \times \nabla |H| \neq 0 \).

![Figure 2](https://example.com/figure2.png)

**Figure 2.** Isotherms (at an interval of 0.1), streamlines (at an interval of \( 1.0 \times 10^{-7} \) stream function) and dimensionless magnetization field strengths (at an interval of \( 1.0 \times 10^{-3} \) with from 0.001 to 0.007) in the case of the electric current wire fixed at \((x, y) = (0, 0)\), where the direction of velocity along the center is leftward.

![Figure 3](https://example.com/figure3.png)

**Figure 3.** Isotherms (at an interval of 0.1), streamlines (at an interval of \( 2.0 \times 10^{-8} \) stream function) and dimensionless magnetization field strengths (at an interval of \( 2.0 \times 10^{-3} \) with from 0.002 to 0.02) in the case of the electric current wire fixed at \((x, y) = (0.15, 0)\), where the direction of velocity along the center is leftward.
Figure 4. Isotherms (at an interval of 0.1), streamlines (at an interval of $1.0 \times 10^{-7}$ stream function) and dimensionless magnetization field strengths (at an interval of $2.0 \times 10^{-3}$ with from 0.002 to 0.02) in the case of the electric current wire fixed at $(x, y) = (0, 0.15)$, where the direction of flow is clockwise.

2) In the case that the electric current wire is fixed in center of annular pipe, two symmetrical circulating flows are produced.

3) If the position of electric current wire is different from the center, the center of the circulating flows moves to the side of lower or higher temperature depending on whether the location of electric current wire is to the lower or higher temperature side. Especially in the case of the position of electric current wire deviates greatly from the median line of temperature, only one circulating flow zone is produced.
