Abstract

In this paper, the robust control problem of general nonlinear multi-input multi-output (MIMO) systems is proposed. The robustness against unknown disturbances is considered. Two algorithms based on the Sliding Mode Control (SMC) for nonlinear coupled Multi-Input Multi-Output (MIMO) systems are proposed: the first order sliding mode control (FOSMC) with saturation (sat) function and the FOSMC with sat combined with integrator controller. Those algorithms were simulated and implemented on the three tanks test-bed system and the experimental results confirm the effectiveness of our control design.

Keywords: Sliding Mode Control, Integrator, Nonlinear Systems, Coupled, Mimo, Uncertain, Liquid Level Control

1. Introduction

The SMC is a widely used approach to design robust control law of uncertain systems. The advantage of such approach is its robustness to parameter variations and disturbances [1,2]. But the major inconvenience of classic sliding mode control is the existence of chattering phenomenon [3], which may induce many undesirable oscillations in control signal. Some attempts on chattering [4] canceling have considered continuous functions instead of sign one. However the provided results lead to a large steady state error which can be reduced using the integral action [5-7]. Moreover even though there exist many works dealing with sliding mode control in the case of Single Input Single Output (SISO) systems [8], there is lack of results when the addressed process is Multi-Input Multi-Output (MIMO) one. This shortage is due to output coupling problem.

In this paper, we propose a first order sliding mode control using Sat function and this control combined with an integrator corrector. Experimental results, operated on a three tank system, are presented to illustrate the effectiveness of the proposed controllers.

The paper is organized as follows. In Section 2 we remind the classical sliding mode control of coupled MIMO nonlinear systems and its robustness to parameter uncertainties and external disturbances. Section three is devoted to SMC with sat function and integral action. The model of the coupled three tanks system and its control is presented in Section 4. The simulation and experimental results are presented in Sections 5 and 6. Finally Section 7 concludes the paper.

2. Sliding Mode Control

Consider a MIMO non linear system with \( p \) inputs and \( m \) outputs defined by the following state representation:

\[
\begin{align*}
\dot{x} &= f(x,t) + g(x,t)u \\
y &= c(x,t)
\end{align*}
\]

(1)

where \( x \) is the \( n \)-dimensional state vector and \( y \) is the \( m \)-dimensional output vector.

\( x = [x_1 \ldots x_n]^T \) and \( y = [y_1 \ldots y_m]^T \) is the \( m \)-dimensional vector, the coefficients of which are nonlinear functions \( c(x,t), f(x,t) \) is the \( n \)-dimensional vector, the coefficients of which are nonlinear functions \( f(x,t), g(x,t) \) is a \( (n \times p) \) matrix with coefficients are the nonlinear functions \( g_i(x,t) \) and \( u \) is the \( p \)-dimensional control vector of coefficients \( u_c \).
\[ u = [u_1 \cdots u_p]^T \] (2)

### 2.1. Classical Sliding Mode Control

Consider the sliding surface \[ s = [s_1 \cdots s_p]^T \] (3)

where:
\[ s_i = \sum_{k=0}^{n-1} \lambda_k^{(i)} x_k^{(i)}, \text{ for } i = 1, \ldots, p \] (4)

with:
\[ r_i \text{ is the relative degree of the error } e_i \text{ and for } k = 1, \ldots, r_i - 1, \lambda_k^{(i)} \text{ are constants chosen so that } \lambda_0^{(i)} + \lambda_1^{(i)} p + \cdots + \lambda_{r_i-1}^{(i)} p^{r_i-1} \text{ is a Hurwitz polynomial one and } e_i^{(k)} \text{ is the } k^{th} \text{ order derivative of the error } e_i. \]

\[ e_i = y_i - y_i^d, \text{ for } i = 1, \ldots, r_i - 1. \] (5)

where \( y_i^d \) is the desired output. The derivative of \( s_i \) is:
\[ \frac{ds_i}{dt} = \sum_{k=0}^{n-1} \lambda_k^{(i)} \left( \frac{de_i}{dt} + \sum_{j=1}^p \frac{\partial e_i}{\partial x_j} \dot{x}_j \right) \] (6)

Replacing \( x_j \) by its expression in (1) and omitting the index \((x,t)\), relation (6) becomes.
\[ \frac{ds_i}{dt} = \sum_{k=0}^{n-1} \lambda_k^{(i)} \left( \frac{de_i}{dt} + \sum_{j=1}^p \frac{\partial e_i}{\partial x_j} f_j + \sum_{j=1}^p \sum_{l=1}^p \frac{\partial e_i}{\partial x_j} g_{jl} u_l \right) \] (7)

which can be written as:
\[ \frac{ds_i}{dt} = h_i + b_i u_i + \cdots + b_p u_p = h_i + \sum_{l=1}^p b_{il} u_i \] (8)

with:
\[ h_i = \sum_{k=0}^{n-1} \lambda_k^{(i)} \left( \frac{de_i}{dt} + \sum_{j=1}^p \frac{\partial e_i}{\partial x_j} f_j \right) \]
\[ b_{il} = \sum_{k=0}^{n-1} \lambda_k^{(i)} \sum_{j=1}^p \frac{\partial e_i}{\partial x_j} g_{jl} \]

Then we can write the derivative of the surface vector as
\[ \dot{s} = h + bu \] (9)

with:
\[ h = \begin{bmatrix} h_1 & \cdots & h_p \end{bmatrix} \text{ and } b = \begin{bmatrix} b_{11} & \cdots & b_{1p} \\ \vdots & \ddots & \vdots \\ b_{p1} & \cdots & b_{pp} \end{bmatrix} \]

**Theorem 1.**

The control law for the first order sliding mode control (FOSMC) of the system 1 so that the sliding surfaces go to zero in a finite time is defined by:
\[ u = -b^{-1} \left( h + \begin{bmatrix} k_1 \text{sign} (s_1) \\ \vdots \\ k_p \text{sign} (s_p) \end{bmatrix} \right) \] (10)

with \( k_i \) a positive constant and \( b \) an invertible matrix.

**Proof.**

Consider the following Lyapunov function:
\[ V = \frac{1}{2} s^T s = \frac{1}{2} (s_1^2 + \cdots + s_p^2) \] (11)

the derivative of \( V \) is:
\[ \dot{V} = s_i \dot{s}_i + \cdots + s_p \dot{s}_p = s^T \dot{s} \] (12)

Using (9) we have:
\[ \dot{V} = s^T (h + bu) \] (13)

Replacing \( u \) by its expression (10) in Equation (9), we obtain:
\[ \dot{s} = \begin{bmatrix} k_1 \text{sign} (s_1) \\ \vdots \\ k_p \text{sign} (s_p) \end{bmatrix} \] (14)

then
\[ \dot{V} = -s^T \begin{bmatrix} k_1 \text{sign} (s_1) \\ \vdots \\ k_p \text{sign} (s_p) \end{bmatrix} = -\sum_{i=1}^p k_i |s_i| \leq 0 \] (15)

Since \( k_i (i = 1, \cdots, p) \) are positive we have \( \dot{V} < 0 \). Then, the Lyapunov function \( V \) tends to 0 and therefore all surfaces \( s_i \) tend to zero, hence the existence of the first order sliding mode.

To prove the finite time convergence of our control we take the Equation (14), we have \( \dot{s}_i = -k_i \text{sign} (s_i) s_i \), then \( s_i \dot{s}_i = -k_i |s_i| \leq -\mu |s_i| \), with \( 0 < \mu < k_i \), which is the \( \mu \) reachability condition [10], then the finite time convergence.

### 2.2. Robustness to Parametric Uncertainties and External Disturbances

Consider an uncertain MIMO nonlinear system:
\[ \dot{x} = f(x,t) + \Delta f(x,t) + \left( g(x,t) + \Delta g(x,t) \right) u + d \] (16)

where \( x \in \mathbb{R}^n \) is the state vector, \( u \in \mathbb{R}^p \) is the input-control bounded as \( |u_i| \leq u_{i_{\text{max}}} \) for \( i = 1 \) to \( p \), the vector field \( f(x,t) + \Delta f(x,t) \) is continuous and smooth, where \( f(x,t) \) is the nominal part and \( \Delta f(x,t) \) is the uncertain part bounded by a known function. \( d \in D \subset \mathbb{R}^n \) represents the disturbances. The dynamic \( g(x) \) is not exactly known and it is written as the sum of the nominal part \( \hat{g}(x,t) \) and the uncertain part \( \Delta g(x,t) \).
with:

\[
\hat{f}(x,t) = \begin{bmatrix} \hat{f}_1(x,t) \\ \vdots \\ \hat{f}_n(x,t) \end{bmatrix}, \quad \hat{g}(x,t) = \begin{bmatrix} \hat{g}_{11}(x,t) \\ \vdots \\ \hat{g}_{np}(x,t) \end{bmatrix}, \quad d = \begin{bmatrix} d_1 \\ \vdots \\ d_n \end{bmatrix}
\]

\[
\hat{d}(x,t) = \begin{bmatrix} \hat{d}_1 \\ \vdots \\ \hat{d}_m \end{bmatrix}
\]

\[
\Delta f(x,t) = \begin{bmatrix} \Delta f_{11}(x,t) \\ \vdots \\ \Delta f_{np}(x,t) \end{bmatrix}, \quad \Delta g(x,t) = \begin{bmatrix} \Delta g_{11}(x,t) \\ \vdots \\ \Delta g_{np}(x,t) \end{bmatrix}
\]

Then the derivative of the sliding surface takes the following form:

\[
\frac{ds}{dt} = \hat{h} + \Delta h + \sum_{k=1}^{p} (\hat{b}_k + \Delta b_k) u_k + \delta_i \tag{17}
\]

then:

\[
\dot{s} = \hat{h} + \Delta h + (\hat{b} + \Delta b) u + \delta
\]

\[
\hat{h}(x,t) = \begin{bmatrix} \hat{h}_1(x,t) \\ \vdots \\ \hat{h}_p(x,t) \end{bmatrix}, \quad \Delta h(x,t) = \begin{bmatrix} \Delta h_1(x,t) \\ \vdots \\ \Delta h_p(x,t) \end{bmatrix}, \quad \delta = \begin{bmatrix} \delta_1 \\ \vdots \\ \delta_p \end{bmatrix}
\]

\[
\hat{b}(x,t) = \begin{bmatrix} \hat{b}_{11}(x,t) \\ \vdots \\ \hat{b}_{1p}(x,t) \\ \hat{b}_{p1}(x,t) \\ \vdots \\ \hat{b}_{pp}(x,t) \end{bmatrix}
\]

and \( \Delta b(x,t) = \begin{bmatrix} \Delta b_{11}(x,t) \\ \vdots \\ \Delta b_{1p}(x,t) \\ \Delta b_{p1}(x,t) \\ \vdots \\ \Delta b_{pp}(x,t) \end{bmatrix} \)

**Theorem 2.**

Consider the uncertain system defined by Equation (16). The control law:

\[
u = -\hat{b}^{-1} \begin{bmatrix} k_i \text{sign}(s_i) \\ \vdots \\ k_p \text{sign}(s_p) \end{bmatrix} \tag{18}
\]

with \( k_i \) satisfying:

\[
k_i > \alpha_i + \delta_i^* + \sum_{k=1}^{m} \beta_k u_{k_{\text{max}}} \tag{19}
\]

and where \( \alpha_i, \beta_k, \delta_i^* \) and \( u_{k_{\text{max}}} \) are the upper bounds of uncertainties, \( \Delta h_i, \Delta b_k, \delta_i \) and \( u_k \) respectively, ensures the finite time convergence of the sliding surface to zero.

**Proof.**

The expression of the derivative of the surface becomes:

\[
\dot{s} = \hat{h} + \Delta h + (\hat{b} + \Delta b) u + \delta \tag{20}
\]

where \( \delta \) is the p-dimensional vector whose coefficients are:

\[
\delta_i = \sum_{j=1}^{p} \frac{\partial \delta_j}{\partial x_j} d_j \quad \text{for } i = 1 \text{ to } p
\]

Using the control expression in (18) we have:

\[
\dot{s} = -\begin{bmatrix} k_i \text{sign}(s_i) \\ \vdots \\ k_p \text{sign}(s_p) \end{bmatrix} + \Delta h + \Delta b u + \delta \tag{21}
\]

The derivative of the surface \( s_i \) is then written:

\[
\dot{s}_i = \Delta h_i - k_i \text{sign}(s_i) + \sum_{k=1}^{p} \Delta b_k u_k + \delta_i \tag{22}
\]

and the derivative of the Lyapunov function given by (12) is:

\[
\dot{V} = \sum_{i=1}^{p} s_i \dot{s}_i
\]

\( \dot{V} \) will be negative if the following conditions are satisfied: \( s_i, \dot{s}_i \leq 0 \) for \( i = 1 \) to \( p \).

If \( s_i > 0 \) then \( \dot{s}_i > 0 \), we have:

\[
\Delta h_i - k_i + \sum_{k=1}^{p} \Delta b_k u_k + \delta_i < 0 \tag{23}
\]

then

\[
\Delta h_i + \sum_{k=1}^{p} \Delta b_k u_k + \delta_i < k_i \tag{24}
\]

If \( s_i < 0 \) then \( \dot{s}_i < 0 \), we have:

\[
\Delta h_i + k_i + \sum_{k=1}^{p} \Delta b_k u_k + \delta_i > 0 \tag{25}
\]

then

\[
-\left( \sum_{k=1}^{p} \Delta b_k u_k + \delta_i \right) < k_i \tag{26}
\]

The conditions (24) and (26) are satisfied if:

\[
\alpha_i + \sum_{k=1}^{p} \beta_k u_{k_{\text{max}}} + \delta_i^* < k_i \tag{27}
\]

then

\[
\dot{V} < 0
\]

3. SMC with Sat

The major inconvenient of classic sliding mode control is the existence of chattering phenomenon. To avoid this...
problem, we approximate the «sign» function by continuous functions such as sat function [9] defined by:
\[
sat(s_i) = \begin{cases} 
s_{i} & \text{if } |s_i| > \varphi_i \\
\frac{s_i}{\varphi_i} & \text{if } |s_i| \leq \varphi_i 
\end{cases}
\] (28)

where \( \varphi_i \) is a positive constant that defines the thickness of the boundary layer.

**Theorem 3.**

The control law for the first order sliding mode control (FOSMC) with sat of the system (1) is defined by:
\[
u = -b^{-1}\left(h + \begin{bmatrix} k_i sat(s_i) \\ \vdots \\ k_p sat(s_p) \end{bmatrix} \right)
\] (29)

with \( k_i \) a positive constant and \( b \) an invertible matrix.

**Proof.**

We consider the same Lyapunov function defined by Equation (11). Its derivative with using control defined in (31) is:
\[
\dot{V} = -s^T \begin{bmatrix} k_i sat(s_i) \\ \vdots \\ k_p sat(s_p) \end{bmatrix}
\] (30)

then
\[
\dot{V} = -\sum_{i=1}^{p} k_i sat(s_i)s_i
\] (31)

Using sat definition given by (28), we have:
\[
sat(s_i)s_i = \begin{cases} 
s_{i}^2 & \text{if } |s_i| > \varphi_i \\
\frac{s_i^2}{\varphi_i} & \text{if } |s_i| \leq \varphi_i 
\end{cases}
\] (32)

Therefore:
\[
sat(s_i)s_i \geq 0
\] (33)

then
\[
\dot{V} < 0
\] (34)

**Remark.**

In the boundary layer the derivative of the surface is:
\[
s_i = \frac{s_i}{\varphi_i}
\] (35)

then
\[
s_i = s_i(t_0) e^{\frac{t-t_0}{\varphi_i}} = \varphi_i e^{\frac{t-t_0}{\varphi_i}}
\] (36)

with:
\( t_0 \) is the start time of boundary layer.

In order to solve a steady-state error problem, an integral sliding manifold was proposed in [10]. This development is introduced and justified only by tests on specific systems. Our idea consists on reconstituting a control law to eliminate steady-state error created by disturbance. To do so we added an integral action when the trajectories of states approach their references [11-14].

**Proposition.**

Consider the uncertain system defined by Equation (1). The control law FOSMC with integrator to eliminate steady-state error is defined by:
\[
u = -b^{-1}\left(h + \begin{bmatrix} k_i sat(s_i) \\ \vdots \\ k_p sat(s_p) \end{bmatrix} \right) + K \int (y_i - y_i^d) \, dt
\] (38)

with
\[
K = \begin{bmatrix} K_{i1} & \cdots & K_{i_p} \\
\vdots & \ddots & \vdots \\
K_{pi} & \cdots & K_{pp} \end{bmatrix}
\]

The coefficients \( K_{ij} \) are the integrator constant defined by:
\[
K_{ij} = \begin{cases} 
\text{positive constant} & \text{if } |y_i - y_i^d| > \varphi_j \\
0 & \text{if } |y_i - y_i^d| \leq \varphi_j 
\end{cases}
\] (39)

with \( \varphi_j \) a positive constant.

### 4. Validation

**4.1. System Description and Modeling**

The considered process is a three tank system, which have two inputs and three outputs. It consists on three cylindrical tanks with identical section \( a \) supplied with distilled water, which are serially interconnected by two cylindrical pipes of identical sections \( S_p \). The pipes of communication between the tanks \( T_1 \) and \( T_2 \) are equipped with manually adjustable valves; the flow rates of the connection pipes can be controlled using ball valves \( az_1 \) and \( az_2 \). The plant has one outlet pipe located at the bottom of tank \( T_3 \). There are three other pipes each installed at the bottom of each tank; they are provided with a direct connection (outflow rate) to the reservoir with ball valves \( bz_1, bz_2 \) and \( bz_3 \), respectively, it can only be manipulated manually. The pumps 1 and 2 are supplied by water from the reservoir with flow rates \( Q_1(t) \) and \( Q_2(t) \), respectively. The necessary level measurements \( h_1(t), h_2(t), h_3(t) \),
The incoming flow and the outgoing flow \( h_2(t) \) and \( h_3(t) \) are carried out by the piezo-resistant differential pressure sensors.

The state Equations are obtained by writing that the variation of the water volume in a tank is equal to the difference between the incoming flow and the outgoing flows, that means, the water of the tanks 1 and 2 can flow toward the tank 3.

Then, the system can be represented by the following Equations:

\[
\dot{h}_i(t) = \frac{1}{A} \left( Q_i^{in}(t) - Q_i^{out1}(t) - Q_i^{out2}(t) \right) \quad i, j = 1, 2, 3 \quad (40)
\]

where \( Q_i^{in}(t) \) is the flow through pump \( i (i = 1; 2) \) and \( Q_i^{out1}(t) \) represents the flow rates of water between the tanks \( i \) and \( j \) \( (i, j = 1, 2, 3 \quad \forall i \neq j) \), and can be expressed using the law of Torricelli[15].

\[
Q_i^{out1}(t) = a_i S_i \sqrt{2g h_i} \quad i, j = 1, 3 \quad (41)
\]

and \( Q_i^{out2}(t) \) represents the outflow rate, given by:

\[
Q_i^{out2}(t) = b_i S_i \sqrt{2g h_i} \quad j = 1, 2, 3 \quad (42)
\]

where \( h_i(t) \), \( Q_i^{in}(t) \) and \( Q_i^{out}(t) \) are respectively the levels of water, the input flow and the output flow rates.

The parameters of three tank system are defined in the Table 1.

The controlled signals are the water levels \( (h_2, h_3) \) of tanks 2 and tank 3. These levels are controlled by two pumps. The system can be considered as a multi input multi output system (MIMO) where the input are inflow rates \( Q_1, Q_2 \) and the output are liquid levels \( h_2, h_3 \). Then the three tank systems can be modeled by the following three differential Equations as shown in (43):

where the parameters \( c_i, i = 1, 3 \) and \( B_j, j = 1, 2, 3, 4 \) are defined by:

\[
c_i = \frac{1}{A} a_i S_i \sqrt{2g} \quad i = 1, 3
\]

\[
B_j = \frac{1}{A} b_j S_j \sqrt{2g} \quad j = 1, 2, 3, 4
\]

While taking \( B_1 = B_2 = B_3 = 0 \), the three Equations of the system become (see Equation (44)):

At equilibrium, for constant water level set point, the level derivatives must be zero.

\[
\dot{h}_1 = \dot{h}_2 = \dot{h}_3 = 0 \quad (45)
\]

Therefore, using (45) in the steady state, the following algebraic relationship holds.

\[
\begin{align*}
-c_i \text{sign}(h_i - h_j) \sqrt{|h_i - h_j|} + \frac{Q_i}{a} &= 0 \\
c_i \text{sign}(h_i - h_j) \sqrt{|h_i - h_j|} - c_i \text{sign}(h_i - h_j) \sqrt{|h_i - h_j|} &= 0
\end{align*}
\]

(46)

For the coupled tanks system, the fluid flow into tank 1, cannot be negative because the pump can only drive water into the tank, then:

\[
Q_1 \geq 0 \quad (47)
\]

From (47) we have

\[
c_i \text{sign}(h_i - h_j) \sqrt{|h_i - h_j|} = \frac{Q_i}{a}
\]

\[
c_i \text{sign}(h_i - h_j) \sqrt{|h_i - h_j|} - c_i \text{sign}(h_i - h_j) \sqrt{|h_i - h_j|} = 0
\]

Then \( (h_1 - h_3) \geq 0 \) and \( (h_3 - h_2) \geq 0 \). Therefore if we assume.

\[
x_1 = h_1, \quad x_2 = h_2, \quad x_3 = h_3, \quad u_1 = Q_1 \quad \text{and} \quad u_2 = Q_2 \quad (48)
\]

We have

\[
\begin{align*}
\dot{x}_1 &= -c_1 \sqrt{|x_1 - x_2|} + \frac{u_1}{a} \\
\dot{x}_2 &= c_2 \sqrt{|x_1 - x_2|} - B_2 \sqrt{|x_2|} + \frac{u_2}{a} \\
\dot{x}_3 &= c_3 \sqrt{|x_2 - x_3|} - c_4 \sqrt{|x_2 - x_3|}
\end{align*}
\]

(49)
which can be written in the same form of (1) as:

$$\begin{align*}
x' &= f(t, x) + gu \\
y &= cx
\end{align*} \quad (50)$$

where

$$x = [x_1 \; x_2 \; x_3]^T, \quad u = [u_1 \; u_2]^T, \quad y = [x_2 \; x_3]^T$$

$$f(t, x) = \begin{pmatrix} -c_1 \sqrt{x_1 - x_3} \\ c_3 \sqrt{x_1 - x_3} - B_1 \sqrt{x_2} - c_3 \sqrt{x_3 - x_2} - c_1 \sqrt{x_1 - x_3} + c_3 \sqrt{x_3 - x_2} \end{pmatrix}, \quad g = \begin{pmatrix} 1/a \\ 0 \\ 1/a \\ 0 \end{pmatrix}$$

$$c = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

4.2. Sliding Mode Control of the Three Tank System

The objective is to regulate the water levels of tank 2 and tank 3 by using both laws defined in Section 3.

The vector of the sliding surface is given by:

$$s = [s_1 \; s_2]^T$$

where:

$$s_1 = (x_2 - x_{2d}) \quad \text{and} \quad s_2 = \lambda (x_3 - x_{3d}) + (\dot{x}_3 - \dot{x}_{3d})$$

$$x_{2d} \quad \text{and} \quad x_{3d} \quad \text{are the desired water levels of tank 2 and tank 3. The derivative of the sliding surface $s_1$ can be written as follows:}$$

$$\dot{s}_1 = l_1 + b_{12} u_2 \quad (51)$$

with:

$$l_1 = \left( c_1 \sqrt{x_3 - x_2} - B_1 \sqrt{x_2 - x_{2d}} \right) \quad \text{and} \quad b_{12} = \frac{\lambda}{a}$$

Similarly, the derivative of $s_2$ is:

$$\dot{s}_2 = l_2 + b_{21} u_1 + b_{22} u_2 \quad (52)$$

with:

$$K = \begin{pmatrix} K_{11} & K_{12} \\ K_{21} & K_{22} \end{pmatrix}$$

5. Simulation Results

The controllers designed in Section 3 are simulated using the MATLAB software. The parameters of the three tank system Figure 1 are given in Table 1. The parameters for the both controls for three tanks are $\lambda = 0.6, k_1 = 0.699, k_2 = 0.53, K_{11} = 10^{-4}, K_{12} = 18.10^{-3}, K_{21} = 7.10^{-4} \quad \text{and} \quad K_{22} = 10^{-4}$. Simulation results are shown in Figures 2 to 4. We can notice that in the absence of chattering in controls $u_1$ and $u_2$ both controls proposed and both output $h_2$ and $h_3$ follows their desired references $h_{2d}$ and $h_{3d}$. However, when we inject a disturbance at $t = 1500$ s in the outflow pipes of tank 2 and tank 3, the two controllers ensure the convergence of the water levels $h_2$ and $h_3$ to their desired references $h_{2d}$ and $h_{3d}$. We see in the Figure 3 when we add integral action, the steady state error is almost eliminated. This is the advantage of the controls proposed in multi-variables coupled system case.
The proposed control algorithms were tested on the physical laboratory plant (Figure 8) consisting of interconnected three tank system. The objective is to control the liquid level of tanks 2 and 3. The experimental schemes have been done under Matlab/Simulink, using Real-Time Interface, and run on the DS1102 DS100 system, which is equipped by a power PC processor. The control algorithm is implemented on DSP (TMS 320C31).

6. Experimental Results

The proposed control algorithms were tested on the physical laboratory plant (Figure 8) consisting of interconnected three tank system. The objective is to control the liquid level of tanks 2 and 3. The experimental schemes have been done under Matlab/Simulink, using Real-Time Interface, and run on the DS1102 DS100 system, which is equipped by a power PC processor. The control algorithm is implemented on DSP (TMS 320C31).

Table 1. Numerical values for physical parameters of the three tank system.

we varied the parameters $c_1$ and $c_3$ by closing and opening a little bit the valves $a_{z1}$ and $a_{z2}$ and we introduce a permanent leakage in the outflow pipes of tank 2 and tank 3 at $t = 1500$ s. We remark at 1500 s in the outflow pipes of tank 2 and tank 3, the two controllers ensure the convergence of the water level $h_3$ and $h_2$ to their desired references $h_{3d}$ and $h_{2d}$ (Figures 9 and 11).

Then, the advantage of the sliding mode control with integrator in simulation and experimental results is the attenuation of error static (Figures 3, 5, 10, and 12).

Moreover, we can also observe that control inputs $Q_1$ and $Q_2$ are smooth and the chattering phenomenon is almost eliminated (Figures 6, 7, 13 and 14).

7. Conclusion

In this paper, robust sliding mode control for a class of MIMO nonlinear systems was presented. In order to eliminate chattering phenomenon and the steady state error induced by the use of sat function, continuous sliding mode control, combined with a conditional integrator
admittance coefficients of various pipes, leakage in the tanks and uncertainty due to neglected pump dynamics, was proposed. This control was applied to the levels control of MIMO nonlinear three tanks system benchmark. The simulation and experimental results show robustness to parameter variations such as tank Section,

The simulation and experimental results, compared with those obtained without integrator, confirm the effectiveness of our control strategy.
