Abstract

The purpose of this study is to optimize the mass of 1.5 MW wind turbine steel tower performing Genetic Algorithm method (GA). In accordance with ASCE 7-98, AISC-89 and IEC61400-1, the impact of loads on tower is calculated within the highest safety conditions against buckling strength of each sections of tower by means of GA codes. The stiffness along tower is ensured entirely while the mass of tower is mitigated and optimized.

Keywords: Mass Optimization, Genetic Algorithm, Wind Turbine Tower

1. Introduction

The cost of wind turbine towers can amount nearly 20-25% of the total investment cost for wind energy plant. Minimization of mass of wind turbine tower has become more crucial job for last two decades. Most modern wind turbines are installed with tubular conical steel towers from the aspect of aesthetics. They are ideally manufactured in 20-30 meters long welded sections and then bolted each other on site [1]. Steel tubular conical towers are manufactured as the tapered steel tower namely these towers have a conical shape with a wider base than the top in general. Such designs increase their strength and saves material. The tower of wind turbine gathers net loads from the tower head and transmits these loads to the foundation. The main load is the axial load on the rotor. Dynamic loading is generated by wind turbulence and constantly by blade tower interaction. The stiffness of tower is based on the tower top weight and the tower height. Additional design requirements have to be satisfied with adequate strength since admissible stresses are not exceeded and for conical towers, shell buckling must be prevented. The existing pre-sized tower is tackled to evaluate as per analysis and design conditions. Steel tower is assumed to be located in Balikesir-Bandirma region in Turkey with 52 m tower height and the 54.7 m tower hub height. The top diameter of tower is 2.56 m and the base diameter tower is 4.3 m.

2. Allowable Stress Design (ASD)

The steel towers are primarily designed and sized to meet the AISC strength design criteria. Allowable stress design method (ASD) is used in lieu of AISC-89 for the steel tubular tower design. The load combination method for the service load (characteristic load) condition is carried out with reference to ASCE-7-98. The allowable bending stress $F_b$ for noncompact section is 0.6 $F_y$, in which the yielding stress $F_y$ of the steel tubular structure is typically 345 MPa (50 ksi). The allowable shear stress $F_v$ is 0.4 $F_y$. The allowable compression stress $F_a$ is represented by the following formula [2]:

$$F_a = \frac{1}{5} \left( 1 - \frac{(K_2^L)^2}{2.5 C_e} \right) F_y$$

where $(KL)^2$ is the slenderness ratio of steel tower, $K = 2$ for the cantilever type of structure, and $L$ and $r$ are the length of the tower and radius of section, respectively. The material coefficient $C_e$ is calculated by:

$$C_e = \sqrt{\frac{2\pi^2E}{F_y}}$$

[1] and [2]
where $E$ is the steel modulus. When $KL/r$ is greater than $C_c$, the allowable compression stress $F_a$ shall be recalculated by:

$$F_a = \frac{12\pi^2E}{23(KL/r)^2} \tag{3}$$

Typically, the ratio of the applied axial compression stress $f_a$ to the allowable compression stress $F_a$ of the steel tower is less than 0.15. The combined stress for the applied bending stress $f_b$ acting on the steel tower shall be satisfied with interaction equation.

$$\frac{f_a}{F_a} + \frac{f_b}{F_b} \leq 1 \tag{4}$$

The applied shear stress $f_v$ from the torsion and the shear force on the tower shall also be less than the allowable shear stress $F_v$ [2].

### 3. Fatigue Load

The DEL (Damage Equivalent Load) method facilitates to determine the steel tower preliminary dimensions in any circumstances which fatigue load histogram data does not exist. The SN curve for the DEL method can be expressed in the following [2]:

$$\log \log \left[ \frac{\Delta s(n)}{\Delta s(80MPa)} \right] = \log \log (80MPa) + 2 \times 10^6 \frac{n}{m} \tag{5}$$

The number of cycles corresponding to the withstand limit along the tower height $z$ can be calculated by using DEL method.

$$N(z) = \frac{M_f(z)}{\Delta \sigma_{max} S(z) \sqrt{N_0}} \tag{6}$$

where:

$M_f(z)$ is the moment produced by the fatigue DEL thrust along steel tower. $S(z)$ is the section modulus that varies along the height of tower. $\Delta \sigma_{max}$ is the maximum allowable stress range at $N_0$ cycles (typically $10^7$) $m$ is the slope of the curve [2].

#### 3.1. Damage Equivalent Load for Steel Tower

There are many fatigue calculation methods. One of which is DEL method in most cases where the full histogram of fatigue cycles is available but only a DEL specified. The DEL is added by a value of SNslope ($m = 4$ used in this circumstance and a number of cycles ($N_0$)).

Total moment range along the tower is calculated as follows:

$$\Delta M_x, y(z) = \max \max (\Delta M_x, yT) - \max \max (\Delta M_x, yB)$$

$$\max \max (\Delta M_x, yT) = \text{Maximum moment range at tower top}$$

$$\max \max (\Delta M_x, yB) = \text{Maximum moment range at tower base}$$

Safety Factor of DEL is 1.0. Consequence failure factor and material factor: $\gamma_{sd}, \gamma_m = 1.15 \times 1.1 = 1.265$

Number of cycles: $5.29 \times 10^8$ for 1.5 MW turbine

This represents a 20 year lifetime.

### 4. Local Buckling Stress

The strength of the tubular steel tower in axial compression is the lesser of the yield strength and the elastic critical buckling stress $\sigma_{cr}$ is calculated:

$$\sigma_{cr} = 0.605E \frac{t}{r} \tag{8}$$

where $r$ is the cylinder radius and $t$ is the wall thickness. However, the presence of imperfections, particularly those introduced by welding, will significantly reduce the tower wall resistance to buckling. As per steel tower design, the reduction coefficient $\alpha_B$ for axial load is found by:

$$\alpha_B = \begin{cases} 0.83 & \text{if } \frac{r}{t} < 212 \\ \sqrt{1 + 0.01 \frac{r}{t}} & \text{if } \frac{r}{t} > 212 \end{cases} \tag{9}$$

The buckling stress $\sigma_u$ can be computed in terms of the yielding stress $F_y$:

$$\sigma_u = \begin{cases} F_y \left( 1 - 0.4123 \left( \frac{F_y}{a_0} \frac{a_{B, \sigma_{cr}}}{a_{B, a_{\sigma_{cr}}}} \right)^{0.6} \right) & \text{if } a_{B, \sigma_{cr}}, a_{B, a_{\sigma_{cr}}} > \frac{F_y}{2} \\ 0.175 a_{B, \sigma_{cr}} & \text{if } a_{B, \sigma_{cr}}, a_{B, a_{\sigma_{cr}}} < \frac{F_y}{2} \end{cases} \tag{11}$$

The maximum applied stress $\sigma_a$ combined with normal stress and shear stress is calculated by $\sigma_a$:

$$\sigma_a = \sqrt{(f_a + f_b)^2 + 3 f_v^2} \tag{12}$$

The unity ratio for the combined stresses is found as follows. Now that the steel tower is liable to combined stress with axial compression and bending moment, the steel tower is designed to satisfy the combined stress check. This check named unity check interaction equa-
tion is carried out in accordance with the AISC manual (ASD 9th Edition).

\[
\frac{f_a}{F_a} + \frac{f_b}{F_b} \leq 1 \quad f_b \leq 0.15 F_b
\]  

where:
- \(f_a\) is the applied compression stress
- \(F_a\) is the allowable stress
- \(f_b\) is the applied bending stress
- \(F_b\) is the allowable bending stress.

5. Earthquake Load

This section is based on ASCE 7-98 Earthquake Load Specification. Even though earthquake load seems to be not much significant effect on design of steel tower because of the fact that wind turbine towers are placed in low seismic areas, earthquake load should be taken into consideration so as to be more precise in designing of steel tubular tower (see Figure 1).

The maximum considered earthquake spectral response acceleration for short periods \((S_{ss})\) and at 1 second \((S_1)\) adjusted for site class effects, should be determined by [3]:

\[
S_{ss} = F_a S_s; S_{M1} = F_v S_i
\]  

where:
- \(S_1\) = Mapped maximum considered earthquake spectral response acceleration at a period of 1s as determined in accordance with Section 9.4.1 (ASCE 7-89).
- \(S_s\) = Mapped maximum considered earthquake spectral response acceleration at short periods as determined in accordance with Section 9.4.1 (ASCE 7-89).
- \(F_a\) and \(F_v\) are defined in Tables 9.4.1.2.4a and b respectively in accordance with Section 9.4.1 (ASCE 7-89).

According to the ASCE 7-89 9.4.1.2.5 design spectral response acceleration at short periods, \(S_{ds}\) and at 1s period \(S_{di}\) shall be determined from Equations 9.4.1.2.5-1 and 9.4.1.2.5-2 respectively:

\[
S_{ds} = \frac{2}{3} S_{ss} ; S_{di} = \frac{2}{3} S_{M1}
\]

From the earthquake geographic map, the maximum considered earthquake (MCE) ground motion for soil site Category B with 5% damping is 1.5 g \((S_s)\) for structures with a short period of 0.2 s and 0.6 g \((S_1)\) for structures with a period of 1 s. The wind turbine towers are typically located in open areas away from population centers with very low occupancy. Because, the occupancy importance factor \((I)\) is equal to 1.0. Site Classification D is assumed for Balikesir-Bandirma/ Marmara Region. Site Classification D is typified by stiff soils with shear velocity \((V_s)\) typically 600–1,200 fps \((183–366 \text{ m/s})\).

\[
F_s = \frac{2}{3} F_v S_s = 1.0g ; S_{di} = \frac{2}{3} F_s S_i = 0.6g
\]

\(F_s\) and \(F_v\) can be defined according to the ASCE 7-98 Table 9.4.1.2.4a-4b respectively. \(F_s\) is the site coefficient as a function of site class and short period MCEg is the acceleration caused by gravity.

\[
S_s(T) = \begin{cases} 
\frac{S_{di}}{T}, & \text{if } T < T_s \\
S_{ds} 0.4 + 0.6 \frac{T}{T_0}, & \text{if } T < T_0 \\
S_{ds}, & \text{Otherwise}
\end{cases}
\]

\[
T_s = S_{ds} / S_{di} ; T_0 = 0.2 T_s
\]

\(T\) is the structural period.

Spectral acceleration response can be found as in Figure 2.

5.1. Design Earthquake Load

The earthquake lateral load affects the whole tower height \(h\) as per its weight distribution [2].

\[
W = \int w(z) dz + W_{Head Mass}
\]

\(w(z)\) is weight distribution as a function of height. \(W\) is the total weight of steel tower with Turbine Head. Base
shear coefficient is,

\[ C_s(T) = Sa(t) \frac{I}{R} \]  \hspace{1cm} (20)

where \( I \) is the importance factor and \( R \) is the reduction factor equal to 1.

Base Shear is \( V = C_s(T)W \) \hspace{1cm} (Figure 3) \hspace{1cm} (21)

The towers are assumed to be located in flat unobstructed area for direct wind exposure Category D where wind flows over the open water and flat terrain.

Importance factor is 1.0 for low occupancy concerning the wind turbine erection and installation.

6. Wind Velocity Pressure

The velocity pressure: \( q_z = 0.613K_zK_qK_rV^2 \left( \frac{N}{m^2} \right) \) \hspace{1cm} (22)

where:

- The topographic factor \( K_z \) is 1.0 for the flat area.
- \( K_q \) is 0.95 for a round cylinder tower in accordance with Table 6-6 in ASCE 7-98.
- The terrain exposure coefficient is determined as per Table 6-5 of ASCE 7-98 or by the following formula [3]:

\[
K_r(z) = \begin{cases} 
2.01(15 \text{ ft})^\frac{z}{z_g} & \text{if } z < 15 \text{ ft} \\
2.01(\frac{z}{z_g})^{\frac{3}{5}} & \text{otherwise} 
\end{cases} \]  \hspace{1cm} (23)

6.1. Direct Wind Load on Tower

The direct wind load on the tower is not only based on the direct wind pressure on the tower but also on the gust factor \( G_f \) and the force coefficient \( C_f \).

\[ G_f = 0.925 \left( 1 + 1.7 \frac{L_z}{g} \right) \left( g_z^2Q^2 + g_z^2R^2 \right) \] \hspace{1cm} (24)

where

- The intensity factor of turbulence:
  \[ I_z = 0.15(33 \text{ ft} / z)^{1/6} \]  \hspace{1cm} (25)

The background response \( Q \) and the resonant response are given in accordance with Eq.6.4 of ASCE 7-98.

\[ Q = \frac{1}{1 + 0.63\left( \frac{B + h}{L_z} \right)^{0.63}} \] \hspace{1cm} (26)

where \( B \) is the horizontal dimension of tower measured normal to wind direction, \( L_z \) is the integral length scale of the turbulence at the equivalent height given by \( L_z = l(z / 33)^{\epsilon} \). \( \epsilon \) and \( l \) are constants listed in Table 6.4 of ASCE 7-98.

\( g_z \) and \( g_Q \) shall be taken as the constant value of 3.4 and \( g_v \) is given by:

\[ g_v = \sqrt{2 \ln(3600\eta_i)} + \frac{0.577}{\sqrt{2 \ln(3600\eta_i)}} \] \hspace{1cm} (27)

The resonant response factor is given by:

\[ R = \frac{1}{\beta} R_x R_y R_z \left( 0.53 + 0.47 R_z \right) \] \hspace{1cm} (28)

\[ R_s = \frac{7.47N_1}{(1+10.3N_1)^{5/3}} \] \hspace{1cm} (29)

The force coefficient \( C_f \) is determined as per Tables 6-10 of ASCE 7-98. Lateral wind load along the tower is calculated by the direct pressure on the projected area which differs with respect to diameter distribution \( d(z) \) of tower.

\[ F_z(z) = q_z G_f C_f d(z) \] \hspace{1cm} (Figure 5) \hspace{1cm} (30)

\[ V_z(z) = \int_z^b F_z(x) dx \] \hspace{1cm} (Figure 6) \hspace{1cm} (31)

\[ M_z(z) = \int_z^b F_z(z)(x-z) dx \] \hspace{1cm} (Figure 7) \hspace{1cm} (32)
Figure 5. Force distributions because of direct wind effect on tower.

Figure 6. Wind shear force along tower.

Figure 7. Wind effect moment along tower.

7. Dynamic Behavior of Steel Tower

Main key consideration in wind turbine design is the avoidance of resonant tower oscillations excited by rotor thrust fluctuations at rotational or blade passing frequency. Natural frequency of tower greater than the blade-passing frequency is said to be stiff on the other hand towers natural frequency between rotational frequency and blade passing frequency are regarded as soft. If the natural frequency, the tower is said to be soft-soft [4].

\[ w_i = 1.75 \sqrt{\frac{E I g}{H^3 (W_i + 0.25 W_{tow})}} \]  

where \( w_i \) is the estimated natural frequency of the tower is the height of tower. \( E \) and \( I \) are elastic modulus and moment of inertia of the tower. \( W_i \) and \( W_{tow} \) are the weight of head mass and tower mass respectively. The natural frequency in Hz is calculated by: \( f_t = \frac{w_i}{2\pi} \)

8. Genetic Algorithm Approach

Genetic Algorithms is one of the methods used in optimization problems. Particularly, it is based on natural selection. Genetic Algorithms is dependent on that the best generation has to live in nature. Although many genetic algorithms have been said with different structures, all of them comprises of three basic operations. Genetic Algorithm uses reproduction, crossover and mutation operators to define fitness and to create new solutions. Reproduction is simply a process to make decision which strings should remain and how many copies of them should be produced in the pool. The decision is made by comparing the fitness of each string. The fitness indicates survival potential and reproduction efficiency of the string in the next generations. For an Optimization problem, the fitness function is the objective function of optimization problem as shown in Figure 8.

9. Optimization Problem

Optimization problems are generally expressed as given in the following:

\[ p_1(x): \text{Margins of safety combined stress (bending stress and shear stress for torsion) because of the wind load effect.} \]

\[ p_2(x): \text{Combined stress (bending stress and shear stress) because of the earthquake load effect.} \]

\[ p_3(x): \text{Natural frequency for the 1st mode bending.} \]

\[ p_4(x): \text{Fatigue stress.} \]

\[ M_{\text{tower}}: \text{Mass of turbine tower.} \]

Minimize

\[ f(x) = M_{\text{tower}}(1 + p_1(x) + p_2(x) + p_3(x) + p_4(x)) \]  

Constraints \( 12 \leq t_i \leq t_i^{+1} \ldots \leq t_i^{+51} \leq 26 \) the thicknesses of sections \( i = 1, 2, \ldots, 51 \)

Figure 11. Design flow.
frequency of tower 1st mode \( w_r \) = Operation frequency of turbine.

Design flow is shown as follows. This GA structure minimizes tower mass subject to general dimensions, design loads and some design restrictions. Load calculation depends on wind turbine design requirements of the standard IEC61400-1 and ASCE 7-98. All extreme loads of tower sections are calculated by the load combination [5] as shown in Figure 11.

10. Optimization Results

Score in figure above represents mass of steel tower in kg. After 40\textsuperscript{th} generation of GA, value of mass levels out. In other words, optimization result has been reached at this point.

11. Conclusions

Each 1 m section along tower represented a chromosome in GA. Each section has been evaluated step by step on the basis of buckling strength in GA. An objective function has been produced by using a genetic algorithm. This optimizes the thickness of steel tower ranging from top 12 mm to base 26 mm in the distribution of pattern. All in all, the thicknesses of tower have been evaluated separately in each 1 m section along the height of the tower. Within the best solution of current conditions, the weight of tower has been obtained 63000 kg with a type of S355J0 material quality. And it gives results for the best solution as indicated above in Figure 12. Moreover, the upcoming studies can be carried out and developed-

Figure 12. Thickness distribution.

further as long as stiffness is obtained.
