Abstract

The paper analyzes power spectral density (PSD) of orthogonal pulse-based signals for time hopping ultra wideband (TH-UWB) systems. Our extensive studies show that the PSD of these signals depends not only on the time dithering code and the modulation schemes, but also on the energy spectral density (ESD) of orthogonal pulses. The different order orthogonal pulses provide different ESD which changes the shape of continuous spectral component with symbols. We show that orthogonal pulse-based signals reduce the dynamic range of amplitude of discrete spectral components. Further, we reduce the dynamic range by adopting longer TH code over orthogonal pulse-based signals. As a result, UWB system performance improves with average transmitted power. The theoretical analysis of PSD of orthogonal pulse-based TH-UWB signal is provided in details and verified through simulation results.

Keywords: Time Hopping Ultra Wideband Radio, Orthogonal Pulse Modulation, Power Spectral Density

1. Introduction

Impulse radio Ultra Wideband (IR-UWB) radio is a promising technology for short range wireless communications. The information is conveyed by short-duration pulse, which has potential to deliver high data rates with low power spectral densities (PSD). Federal Communication Commission (FCC) has limited the PSD of the signal to $-41.25$ dBm/MHz in the band from 3.1 GHz to 10.6 GHz. However, the UWB signal interferes with other radio signals due to its noise like signal characteristic. The power distribution of UWB signal over a large bandwidth can be identified by analyzing the PSD of the signal. The reduction of PSD of UWB signal reduces UWB interference on narrowband (NB) systems and keeps UWB signal under the FCC spectral mask [1].

Recently, orthogonal pulses have taken a lot of attention in time hopping UWB (TH-UWB) systems [2]. Several modulation schemes such as pulse shape modulation (PSM), combined on-off-keying (OOK) and PSM, called OOK-PSM, combined PSM and pulse position modulation (PPM), called PSM-PPM, combined orthogonal PPM (OPPM) and bi-orthogonal PSM (BPSM), called OPPM-BPSM, have been proposed to simplify the TH-UWB systems [3-5]. The orthogonal pulse-based modulation schemes are becoming more popular due to the simplicity of newly developed pulse designed algorithms [6,7]. The efficiency of these orthogonal pulses is studied in [8,9]. The spectral characteristic of these orthogonal pulses is provided in [10]. However, only few papers described the PSD of orthogonal pulse-based modulation schemes.

In this paper, we analyze the power spectral density of orthogonal pulse-based TH-UWB signal for PSM, BPSM, OPPM-PSM and OPPM-BPSM schemes. We show that orthogonal pulse-based modulation schemes adjust the continuous power spectrum component with FCC limitation and reduce the dynamic range of the amplitude of the discrete spectral components. Again we smooth the PSD of the signal by employing longer TH code over the orthogonal pulse-based modulation. The simulation results are provided for PSD of TH-UWB signal for OPPM and OPPM-PSM schemes based on modified Hermite pulses (MHPs).

The rest of the paper is organized as follows. Section 2 discusses a generalized orthogonal pulse-based TH-UWB signal. Section 3 presents derivation of PSD of orthogonal pulse-based TH-UWB signal. Section 4 characterizes PSD of TH-UWB signal for PSM, BPSM and OPPM-BPSM schemes. In Section 5, simulation results and discussion are provided. Finally, conclusion is drawn in Section 6.
2. Generalized Orthogonal Pulse-Based UWB Signal Model

In M-ary PSM scheme, different symbols are transmitted by different order orthogonal pulses. It requires M orthogonal pulses at the transmitter and M correlators at the receiver. In M-ary BPSM scheme, symbols are transmitted by using positive or negative amplitude of the orthogonal pulses. It requires M/2 orthogonal pulses at the transmitter and M/2 correlators at the receiver to transmit and receive all M possible symbols. In OPPM-BPSM scheme, M symbols are transmitted by using L pulse positions and N biorthogonal pulses where \( M = 2^{l} \), \( L = 2^{l} \) and \( N = 2^{k-l-1} \) [5].

OPPM-BPSM is a generalized modulation scheme of PSM, BPSM, OPPM-PSM and OPPM-PSM scheme [5]. By changing the number of pulse positions and orthogonal pulses, one can construct a wide variety of modulations. For example, M-ary OPPM scheme can be designed by using one pulse position and M orthogonal pulses whereas an M-ary BPSM can be constructed by using one pulse position and M/2 biorthogonal pulses. M-ary OPPM-PWM can be constructed by using L positions and 2N orthogonal pulses.

Since PSM, BPSM and OPPM-PSM are particular cases of OPPM-BPSM, only OPPM-BPSM signal model is provided. The M-ary OPPM-BPSM signal for \( k \)th user is given as

\[
\sum_{j=0}^{M-1} w_{i}^{(j)}(t-jT_{f}) - c_{i}^{(j)}T_{c} - \delta_{i}^{(j)}
\]

where \( j \) is the index of time frame, \( E_{m} \) is the transmitted energy of the signal and \( d_{m} \in \{ \pm 1 \} \), \( m = 1,2 \) is the amplitude of pulse \( w_{i}^{(j)}(t) \), \( n \) represents the order of the orthogonal pulse. The pulses have finite energy and are normalized to ensure equal energy per transmission, that is \( \int_{0}^{T_{f}} w_{i}^{(j)}(t)^{2} dt = 1 \) where \( 0 \leq n \leq M \). The pulse repetition interval \( T_{f} \) is divided into \( N_{f} \) time slots of length \( T_{c} \), where \( N_{f}T_{c} \leq T_{f} \), \( c_{i}^{(j)} \) is a pseudorandom TH code sequence, and \( 0 \leq c_{i}^{(j)} < N_{f} \). \( \delta_{i}^{(j)} \) is the additional time shift from nominal position. For PSM scheme, \( n = 0,1,\ldots,M-1 \), \( d_{m} = 1 \) and \( \delta_{i}^{(j)} = 0 \). For BPSM scheme, \( n = 0,1,\ldots,M/2-1 \), \( d_{m} = \pm 1 \) and \( \delta_{i}^{(j)} = 0 \). For OPPM-PSM scheme, \( n = 0,1,\ldots,N \), \( d_{m} = 1 \) and \( \delta_{1} < \delta_{2} < \cdots < \delta_{N} < T_{c} \) where \( \delta_{1} = 0 \). For OPPM-BPSM scheme, \( d_{m} = \pm 1 \) and other terms are same as OPPM-PSM.

3. Power Spectral Density Analysis

In orthogonal pulse based signal, different symbols are transmitted by different order orthogonal pulses. The continuous spectrum, energy spectral density (ESD), changes with symbol. The discrete spectral component changes with orthogonality of the pulses and TH code. Therefore, a mathematical framework is essential to understand the orthogonal pulse based PSD in the presence of deterministic TH code. We assume that the analysis is only for 1 user. For simplicity, the superscript/subscript terms in (1) are omitted/modified. After some modification, sum of \( M \) symbol can be written from (1) as

\[
s_{p}(t) = \sum_{l=0}^{M-1} \sum_{k=0}^{N_{f}-1} a_{l}w_{l}(t-lN_{f}T_{f} + hT_{f} - c_{i,h}T_{c} - \delta_{i})
\]

where \( a_{l} \) is the amplitude and \( \delta_{i} \) is the pulse position. The terms \( a_{l} \), \( \delta_{i} \) and \( w_{l} \) are independent and stationary process. The index \( p \) is related to TH code, \( c_{i,h} \), and TH period, \( N_{f} \). To simplify the analysis of the PSD of TH-UWB signal, it is assumed that the number of time frames for a symbol is \( N_{f} \) and it is equal to \( N_{p} \). Since (2) depends on the time dithering, it can be written in continuous form as

\[
y(t) = \sum_{p} s_{p}(t - lN_{f}T_{f}).
\]

The PSD is computed by evaluating the Fourier transform (FT) of the autocorrelation function of \( y(t) \), i.e.,

\[
P_{y}(f) = \mathcal{F}\{E[y(t)y(t+\tau)]\}
\]

where \( \mathcal{F}\{\cdot\} \) denotes the FT and \( E\{\cdot\} \) denotes the expectation operator. Therefore, the PSD can be expressed as [11].

\[
P_{y}(f) = \frac{1}{N_{f}T_{f}} \left[ E[|S_{p}(f)|^{2}] - E[S_{p}(f)]^{2} \right] + \frac{1}{(N_{f}T_{f})^{2}} \sum_{k} E[|S_{p}(f)S_{p}^{*}(f)|\delta(f - k/N_{f}T_{f})]
\]

where \( p \) and \( q \) are two independent random variables with the same probability distribution function. \( S_{p}(f) \) is the FT of \( s_{p}(t) \). It can be expressed as

\[
S_{p}(f) = \sum_{i=0}^{M-1} W_{i}(f)T_{f}a_{i}e^{-j2\pi f t}
\]

where \( W_{i}(f) \) is the FT of the transmitted pulse \( w_{i}(t) \). The time domain representation of \( (l+2) \)th order MHPs can be expressed as

\[
aw_{l+2}(t) = 2aw_{l+1}(t) - 2(l+1)w_{l}(t)
\]

The FT of \( w_{l+1}(f) \) can be expressed as

\[
W_{l+1}(f) = j\frac{1}{4\pi}W_{l}(f) - 2\pi f W_{l}(f)
\]

where “·” stands for derivative with respect to fre-
quency. For MHP, \( W_0(f) \) is defined as
\[
W_0(f) = 2\sqrt{\pi} e^{-\frac{1}{2} f^2}
\]  
(9)

The time and frequency domain representation of MHPs are given in Figure 1.

\( T_l(f) \) is the FT of the TH code which transmits the \( l \)th symbol
\[
T_l(f) = \sum_{n=0}^{N_k-1} e^{-j2\pi f (t_n T_e + (N_p n) T_f)}. \tag{10}
\]

To find the closed form expression of \( P_s(f) \) in (5), the expectation of \( |S_p(f)|^2 \) is to be evaluated. It is given as
\[
E\{s_p(f) s_p^*(f)\} = \sum_{n=0}^{M-1} \sum_{a=0}^{M-1} W_a(f) W^*_a(f) T_l(f) \sum_{l=0}^{M-1} |W_l(f)|^2 T_l(f) T^*_l(f) \tag{11}
\]

Since \( a_l \) and \( a_n \) are independent random variables derived from the same process and \( \delta_l \) and \( \delta_n \) are independent random variables derived from different processes. Therefore, (11) can be rewritten as
\[
E\{s_p(f) s_p^*(f)\} = \sum_{n=0}^{M-1} \sum_{a=0}^{M-1} W_a(f) W^*_a(f) T_l(f) \sum_{l=0}^{M-1} |W_l(f)|^2 T_l(f) T^*_l(f) \tag{12}
\]

Similarly, the second expectation in (5) can be expressed as
\[
E\{s_p(f) s_q^*(f)\} = \sum_{n=0}^{M-1} \sum_{a=0}^{M-1} W_a(f) W^*_a(f) T_l(f) T^*_l(f) \sum_{l=0}^{M-1} |W_l(f)|^2 T_l(f) T^*_l(f) \tag{13}
\]

4. Characterization of PSD of TH-UWB Signal

Although UWB signals are alike in the frequency domain, they are diverse in the time domain due to their different characteristics of time domain parameters \( N_p \), \( T_f \), \( a_l \) and \( w_j \). We see that the PSD of orthogonal pulse-based modulation signals consists of continuous and discrete spectral components which change with the order of pulse waveforms and modulation schemes. The variations of PSD over different orthogonal pulse-based signaling are given in the following subsection.

4.1. PSD of M-ary Pulse Shape Modulation (PSM)

In PSM scheme, symbols are modulated only by the order of orthogonal pulses. The generalized terms in (15) are specified by \( a_i = 1 \) and \( \delta_i = 0 \). The expectations of these variables are \( E[a_i] = 1 \), \( E[a_i] = 0 \) and \( E[e^{-j2\pi (\delta_i - \delta_n)}] = 1 \) respectively. The PSD of the PSM signal can be written from (15) as
\[
P_s(f) = p(f) + P_i(f) \tag{16}
\]
where
\[
p(f) = N_p T_f \sum_{l=0}^{M-1} |W_l(f)|^2 T_l(f) \tag{17}
\]
We see that \( p(f) \) is continuous spectrum component. It depends on the TH code and the ESD of the \( l \)th order orthogonal pulse. Since ESD of different order orthogonal pulses are not identical, the selection of order of the orthogonal pulses plays an important role for continuous spectral component.

\[ p(f) = 1(N_p T_f) \sum_{j=0}^{M-1} \sum_{k=0}^{N_j-1} W_j(f) W_j^*(f) T_j T_j^*(f) \times \sum_k \delta(f - kN_j T_f) \]  

(18)

4.2. PSD of \( M \)-ary Biorthogonal PSM (BPSM)

In BPSM scheme, symbols are modulated by order and amplitude of the pulses, i.e., \( a_i \in \{ \pm 1 \} \) and \( \delta_1 = 0 \). The expectation of these variables are \( E[a_i^2] = 1 \), \( E[a_i a_{i+n}] = 0 \) and \( E[e^{-j2\pi f\delta}] = 1 \).

The corresponding PSD of BPSM scheme can be expressed from (15) as

\[ P_p(f) = 1N_p T_f \sum_{j=0}^{M-1} \sum_{k=0}^{N_j-1} |W_j(f)|^2 \times \exp(-j2\pi f((c_{j,h} - c_{j,k})T_c + (h-k)T_f)) \]  

(19)

The continuous PSD component of BPSM signal is same as PSM scheme. However, the discrete spectral components become zero due to the antipodal pulse. The PSD of the TH-UWB signal for BPSM scheme is smoothed. This allows the signal to coexist with other NB signals. The extensive studies found that any antipodal signal has only continuous spectral component [12]. The continuous component can be easily fitted to FCC by using appropriate MHPs.

4.3. PSD of \( M \)-ary OPPM-BPSM

For OPPM-BPSM scheme, \( a_i \in \{ \pm 1 \} \) and \( \delta_i = (l-1)\delta \), where \( \delta \) is the constant time shift length. This implies, \( E[a_i^2] = 1 \), \( E[a_i a_{i+n}] = 0 \) and \( E[e^{-j2\pi mf T \delta}] = (1 + \cos(2\pi mf T \delta))/2 \).

The corresponding PSD of OPPM-BPSM signal can be expressed as

\[ P_p(f) = 1N_p T_f \sum_{l=0}^{M-1} \sum_{n=0}^{N_l-1} |W_l(f)|^2 \times \exp(-j2\pi f((c_{l,h} - c_{l,k})T_c + (h-k)T_f)) \]  

(20)

The PSDs of BPSM and OPPM-BPSM schemes are identical. However, OPPM-BPSM can be used for higher level modulation scheme for higher data rate systems. Therefore, OPPM-BPSM modulation is an attractive choice of TH-UWB signal from several aspects.

5. Simulation Results and Discussions

In this section, PSD is provided for orthogonal pulse-based signaling and compared with conventional OPPM scheme. In simulation, different orders of MHPs are used with two different lengths of TH code 8 and 16. The other simulation parameters are set to \( T_f = 60 \) ns and pulse width is 7 ns.

Since BPSM and OPPM-BPSM have antipodal signal, they have only continuous spectral component and shape of their spectral is same as continuous component of non antipodal signal. The only difference is that the spectral of antipodal signal does not contain any discrete component. The PSD in non antipodal modulation schemes is more complicated. Since OPPM and OPPM-PSM are special cases of OPPM-BPSM, OPPM and OPPM-PSM have been chosen to compare the PSD of the signal. The PSD of 8-ary OPPM is given in Figure 2 for 3rd order pulse and in Figure 3 for 4th and 5th order pulses with TH code of length 8 and \( T_c = 7.5 \). Since each time only one pulse is used in OPPM scheme, orthogonality is maintained by position not by pulse. The 3rd order pulse almost satisfies the FCC spectral mask except some discrete components. However, 4th and 5th order pulses do not satisfy the FCC spectral mask shown in Figure 3. The dynamic range of the amplitude of discrete components of OPPM scheme is about 8 dB which is very high. The power of the signal is calculated based on the line where the dynamic range is zero (4 dB bellow from the pick point). As FCC rules, pick amplitude must be bellow the –41.25 dBm limit. Therefore, the power of the signal is calculated based on the line which is maximized up to –45.25 dBm. As a result, signal provides low average transmitted power which degrades the system.
Figure 2. PSD of 8-ary OPPM scheme with 3rd order MHP and TH code length is 8.

Figure 3. (a) PSD of 8-ary OPPM scheme with 4th order MHP; (b) PSD of 8-ary OPPM scheme with 5th order MHP and TH code length is 8.
Figure 4. PSD of 8-ary OPPM-PSM schemes for 4 positions and 5 pulses (0th and 3rd) with TH code of length 8.

Figure 5. PSD of 8-ary OPPM-PSM schemes for 4 positions and 2 pulses 0th and 3rd with TH code of length 16.
performance. Not that if the dynamic range becomes zero, the maximum limit becomes \(-41.25\) dBm.

Figure 4 shows the PSD of 8-ary OPPM-PSM for 4 positions and 2 orthogonal pulses with TH code of length 8. We see that that dynamic range of the amplitude of the discrete spectral component of OPPM-PSM scheme is 4 dB which is lesser than the OPPM scheme even the same length of TH code is used. It is because of the orthogonality of pulses. So by reducing dynamic range, we can improve the UWB system performance by increasing the average transmitted power in the signal pulse as well as we can reduce the UWB interference over other radio systems. Again by applying TH code over these orthogonal pulse-based modulations, dynamic range of amplitude of discrete component further could be reduced. Figure 5 shows the PSD of 8-ary OPPM-PSM with TH code of length 16 and \(T_e = 3.75\). The dynamic range is almost reduced to 1 dB. However, it can not be reduced to zero whatever the length of TH code used. We also see that the average transmitted power in Figure 5 is more than the previous cases. Therefore, orthogonal pulse-based TH-UWB signaling has several advantages than its complexity burden.

6. Conclusion

PSD of orthogonal pulse-based TH-UWB signal has been analyzed based on stochastic signal theory. This shows that the continuous and discrete components change with order of pulses and modulation schemes. The discrete component can be removed by employing an antipodal signal. If the signal is not antipodal, the dynamic range of amplitude of the discrete component can be reduced by using orthogonal pulse-based modulation and long TH code. Therefore, it has been proved that the orthogonal pulse-based signaling not only reduce the dynamic range of discrete spectral component also improve the system performance by increasing the average transmitted power in the signal.
