Abstract

The ground plan in order to disentangle the hard problem of modelling the motion of a bicycle is to start from a very simple model and to outline the proper mathematical scheme: for this reason the first step we perform lies in a planar rigid body (simulating the bicycle frame) pivoting on a horizontal segment whose extremities, subjected to nonslip conditions, oversimplify the wheels. Even in this former case, which is the topic of lots of papers in literature, we find it worthwhile to pay close attention to the formulation of the mathematical model and to focus on writing the proper equations of motion and on the possible existence of conserved quantities. In addition to the first case, being essentially an inverted pendulum on a skate, we discuss a second model, where rude handlebars are added and two rigid bodies are joined. The geometrical method of Appell is used to formulate the dynamics and to deal with the nonholonomic constraints in a correct way. At the same time the equations are explained in the context of the cardinal equations, whose use is habitual for this kind of problems. The paper aims to a threefold purpose: to formulate the mathematical scheme in the most suitable way (by means of the pseudovelocities), to achieve results about stability, to examine the legitimacy of certain assumptions and the compatibility of some conserved quantities claimed in part of the literature.

Keywords

Nonholonomic Constraints; Lagrangian Equations; Pseudovelocities; Nonlinear Order Differential Equations; Stability

1. Introduction

1.1. The Equations of the Model

A very simple scheme can be formulated by assuming that the body is a planar rigid system \( \mathbb{P} \) sketched by three points \( A, B \) and \( P_0 \); \( A \) and \( B \), performing the two contact points of the wheels, belong to a horizontal plane and \( P_0 \) is the centre of mass of \( \mathbb{P} \). The rigid body can lean with respect to the vertical direction and bend with...
respect to a fixed horizontal direction. Let \( O \) be the projection of \( P_0 \) on \( B - A \) and take a fixed reference frame \( \{ \Omega, \{e_1, e_2, e_3\} \} \), \( e_1 \) being the upward vertical, and a body reference frame \( \{0, \{i, j, k\}\} \) such that \( \psi \) is the angle \( e_1 \), \( \theta \) is the angle \( k e_3 \). The mutual disposal of the two frames is given by

\[
\begin{align*}
i &= \cos \theta e_1 + \sin \theta e_2, \\
j &= \cos \psi (\cos \theta e_1 + \sin \theta e_2) + \sin \theta e_3, \\
k &= \sin \psi (\cos \theta e_1 + \sin \theta e_2) + \cos \theta e_3,
\end{align*}
\]

and sketched in Figure 1.

Set \( O - \Omega = \xi_0 e_1 + \eta_0 e_2 \); the geometrical restrictions \( |A-O| = a \), \( |B-O| = b \), \( |P_0 - O| = h \) lead us to consider the four lagrangian coordinates \( (\xi_0, \eta_0, \psi, \theta) \). Therefore \( P_0 - \Omega = (\xi_0 + h \sin \theta \sin \psi)e_1 + (\eta_0 - h \sin \theta \cos \psi)e_2 + h \cos \theta e_3 \). The angular velocity of the rigid body is \( \omega = \dot{\theta} i + \psi e_1 \).

The Lagrangian function of the system writes

\[
\mathcal{L} = T + U = \frac{1}{2} m \dot{\xi}_0^2 + \frac{1}{2} \left( I_0 \dot{\psi}^2 + \psi^2 \left( I_1 \sin^2 \theta + I_k \cos^2 \theta \right) \right) - mgh \cos \theta
\]

where \( I_0 = \xi_0^2 + \eta_0^2 + h^2 \left( \psi^2 \sin^2 \theta + \hat{\psi}^2 \right) + 2h (\dot{\psi} \sin \theta (\dot{\xi}_0 \cos \psi + \dot{\eta}_0 \sin \psi) + \dot{\theta} \cos \theta (\dot{\xi}_0 \sin \psi - \dot{\eta}_0 \cos \psi)) \) and \( I_1 \), \( I_k \) are the moments of inertia with respect to the body reference frame \( \{P_0, i, j, k\} \), which is supposed to be principal.

The only kinetic constraint we are going to consider is \( B \land i = \theta \), whose expression in the Lagrangian coordinates is

\[
b \dot{\psi} + \dot{\xi}_0 \sin \psi - \dot{\eta}_0 \cos \psi = 0.
\]

The first kind Lagrangian equations of motion

\[
\begin{align*}
\frac{d}{dt} \nabla_q \mathcal{L} - \nabla_q \mathcal{L} &= \lambda (\sin \psi, -\cos \psi, b, 0), \\
bn \dot{\psi} + \dot{\xi}_0 \sin \psi - \dot{\eta}_0 \cos \psi &= 0,
\end{align*}
\]

where \( q = (\xi_0, \eta_0, \psi, \theta) \) are the lagrangian coordinates and \( \lambda \) is the unknown multiplier, will be suitably handled if one defines the pseudovelocities (see [1] for the concepts and the method we are pursuing)

\[
\begin{align*}
U &= (\xi_0 \cos \psi + \dot{\eta}_0 \sin \psi) / b, \\
V &= (-\dot{\xi}_0 \sin \psi + \dot{\eta}_0 \cos \psi) / b, \\
W &= \dot{\theta}
\end{align*}
\]

We point out the following relationships involving \( U, V \) and the real velocities:
\[
\dot{\mathbf{B}} = b\mathbf{U}\dot{\mathbf{O}} = b(\mathbf{U}\dot{\mathbf{V}}_j),
\mathbf{A} = b(\mathbf{U}(1 + \alpha)\mathbf{V}_j),
\]  
where \(\alpha = a/b\) and \(j_j = e_i \wedge i = -\sin\psi e_j + \cos\psi e_k = \cos \theta j - \sin \theta k\).

Together with the kinetic constraint, Equations (4) give the set of possible velocities in terms of \(\mathbf{U}, \mathbf{V}, \mathbf{W}\):

\[
\dot{\mathbf{q}} = \begin{pmatrix}
\dot{\xi}_0 \\
\dot{\eta}_0 \\
\dot{\psi} \\
\dot{\phi}
\end{pmatrix} = \begin{pmatrix}
bcos\psi & -b\sin\psi & 0 \\
b\sin\psi & b\cos\psi & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{pmatrix} \begin{pmatrix}
\mathbf{U} \\
\mathbf{V} \\
\mathbf{W}
\end{pmatrix}
\tag{6}
\]

It is known (see [1]) that linear kinetic constraints allow to refine the equations of motion (3) in a way similar to the holonomic case: as a matter of fact, the constraints identify a subspace in the tangent space of the lagrangian coordinates, giving the virtual displacement of the system. The geometrical method consists of projecting the equations according to

\[
\Gamma^T \left( \frac{d}{dt} \mathbf{L} - \nabla_s \mathbf{L} - \nabla_s \mathbf{L} \right) = 0
\]
where \(\Gamma\) is defined in (6). Joining to the kinetic constraint (2) and the definition (4) we get, dividing by suitable constants,

\[
\begin{align*}
\dot{U} + \bar{h}V \sin \theta - V^2 + 2\bar{h}W \cos \theta &= 0 \\
\bar{h}U \sin \theta + (1 + T \sin^2 \theta) \dot{V} - \bar{h}W \cos \theta + UV + \bar{h}W^2 \sin \theta + 2TV \cos \theta \sin \theta &= 0 \\
-\bar{h}V \cos \theta + (\bar{T} + \bar{h}^2) \dot{W} - TV^2 \cos \theta \sin \theta - \bar{h}UV \cos \theta - (g\bar{h}/b) \sin \theta &= 0 \\
\theta &= W \\
\dot{\xi}_0 &= b(U \cos \psi \sin \psi), \dot{\eta}_0 = b(U \sin \psi + V \cos \psi), \dot{\psi} = V
\end{align*}
\tag{7}
\]

where

\[
\bar{h} = h/b, \bar{T} = (m_2^2 + I_j - I_k) / mb^2, \bar{T}_j = I_j / mb^2
\tag{8}
\]
are dimensionless constants. Since the rigid body is practically plane and contained in the plane orthogonal to \(j\), it is reasonable to assume \(I_j > I_k\), \(I_j + I_k = I_j\), so that

\[
\bar{T} > 0, \bar{T}_j + \bar{T}_k = \bar{T}.
\tag{9}
\]

From here on we adopt (9).

The seven ODEs (7) contain the seven unknown quantities \((U, V, W, \xi_0, \eta_0, \psi, \theta)\). With respect to the first kind system (3) they have the advantage of no exhibiting multipliers and of reducing the kinetic variables of one unity.

It is not at all worthless to explain (7) in the context of the the cardinal equations of dynamics, seeing that many models in literature (some of them are [2]-[5]) rest on such equations: the first three equations in (7) are respectively

\[
\begin{align*}
\dot{m}p_0 \cdot \dot{\xi} &= 0 \\
(\dot{\mathbf{L}}(B) + B \wedge m\dot{p}_0) \cdot e_j &= 0 \\
(\dot{\mathbf{L}}(O) + O \wedge m\dot{p}_0) \cdot \dot{i} &= M^{(i)}(O) \cdot \dot{i}
\end{align*}
\]

where \(\mathbf{L}\) is the angular momentum and \(M^{(i)}\) the resultant momentum of the external forces. Actually, no friction is present, the constraint \(\Phi_j\) in \(A\) is along \(e_j\), while the constraints in \(B\) can be modelled as a force \(\Phi_{\beta}\) along \(e_3\), plus a horizontal force \(\Phi_{\beta}^{(i)}\) perpendicular to \(B = A\) (see Figure 2), acting the constraint (2):

\[
\Phi_j = \phi_j e_j, \Phi_{\beta} = \phi_{\beta} e_3, \Phi_{\beta}^{(i)} = \phi_{\beta}^{(i)} j.
\tag{10}
\]

Hence no force exists along \(i\) (first equation) and \(M^{(i)}(B) \cdot e_i = 0\) (second equation), along \(e_3\) (and not \(k\), as stated in [6]). Finally, third equation is simply due to the fact that the only external force with a non zero momentum along \(i\) is the weight force.

Notice that any of the three equations do not give rise to a conserved quantity: the only evident constant of
motion is the total energy $\mathcal{E} = T - U = \mathcal{E}_0$:

$$\frac{1}{2} \left( U^2 + (1 + \overline{T}_k + \overline{T}_\sin^2 \theta) V^2 + \overline{W}^2 \right) + \overline{W} V \left( U \sin \theta - W \cos \theta \right) + \left( g \overline{R} / b \right) \cos \theta = \mathcal{E}_0 / (mb^2). \quad (11)$$

Actually, even if the system is nonholonomic, the first integral $\mathcal{E} = \mathcal{E}_0$ can be achieved starting from

$$0 = \Gamma^t \left( \frac{d}{dt} \nabla_q \mathcal{L} - \nabla_q \mathcal{L} \right) \cdot \begin{pmatrix} U \\ V/W \end{pmatrix} = \left( \frac{d}{dt} \nabla_q \mathcal{L} - \nabla_q \mathcal{L} \right) \cdot \dot{q} \quad \text{and performing the usual calculations as in the holonomic case, achieving at last} \quad \mathcal{E} = 0.$$

In the same matter of integral invariants for the system, we find it not correct to claim, as in [7], that the absence of $\dot{\xi}_0$, $\dot{\eta}_0$, $\psi$ from $\mathcal{L}$ entails three constant of motion, in order that four conserved quantities (including the total energy) can be obtained: as a matter of fact, the equations of the model are not $\frac{d}{dt} \nabla_q \mathcal{L} \cdot \dot{q} = 0$ and cyclic variable does not mean conserved quantity. Besides that, even if $\mathcal{L}$ is written in terms of $U$ and $V$, $\psi$ is not a cyclical coordinate, being implicitly in such variables. For this reason we question the validity of

$$0 = \frac{d}{dt} \frac{\partial \mathcal{L}}{\partial \dot{\psi}} = U + \overline{W} \sin \theta + \overline{W} W \cos \theta \quad \text{(Equation (14) in [7])}, \quad \text{which would imply an integral invariant.}$$

With regards to the same subject, we emphasize that equation

$$0 = \frac{d}{dt} \frac{\partial \mathcal{L}}{\partial \dot{U}} = U + \overline{W} \sin \theta + \overline{W} W \cos \theta \quad \text{(Equation (16) in [7])}, \quad \text{giving rise to the conservation of} \quad U + \overline{W} \sin \theta, \quad \text{is not correct in our advice, since} \ U \not \text{ does not refer to a lagrangian coordinate.}$$

1.2. The Mathematical Problem

We perform now a brief analysis of (7). It is evident that the first four equations in (7) form the sub-system

$$A(\theta) \dot{X} = F(X), \quad X = (U,V,W,\theta), \quad A = \begin{pmatrix} 1 & \overline{W} \sin \theta & 0 & 0 \\ \overline{W} \sin \theta & 1 + \overline{T}_k + \overline{T}_\sin^2 \theta & -\overline{W} \cos \theta & 0 \\ 0 & -\overline{W} \cos \theta & \overline{T} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad F(X) = \begin{pmatrix} V \left( V - 2 \overline{W} \cos \theta \right) \\ -UV - W \sin \theta \left( \overline{W} + 2 \overline{V} \cos \theta \right) \\ V \cos \theta \left( \overline{V} \sin \theta + \overline{H} U \right) + \left( g \overline{R} / b \right) \sin \theta \\ W \end{pmatrix}. \quad (12)$$
The last three equations in (7) give simply $\xi_0$, $\eta_0$, $\psi$ once (12) has been solved.

**Statement 1.1** System (7) admits locally one solution, for any set of data $\xi_0(0)$, $\eta_0(0)$, $\psi(0)$, $\theta(0)$, $U(0)$, $V(0)$, $W(0)$.

**Proof.** The assigned data provide $q(0)$ and $q(0)$, by means of (6). Furthermore

$$\det A = T(1 + T_e + T \sin^2 \theta - \bar{h}^2) = T \left[ 1 - \kappa + T_e + \left( 1 - \kappa + (\kappa/T) \right) T \sin^2 \theta \right] > 0,$$

where we defined (see also (8) and (9))

$$\kappa = \frac{\bar{h}^2}{T} < 1.$$  

Therefore (12) can be solved in an appropriate time interval. Finally one obtains $\xi_0$, $\eta_0$ e $\psi$ from the last three equations in (7) and the rest of the given data. □

**Remark 1.1** If in (7) we let $h = 0$, we are dealing with the simpler case of a bar on a horizontal plane with one point moving at each time along the direction of the bar: since $I = 0$, equations reduce to

$$\begin{cases}
U = V^2 \\
(1 + T_k) V = -UV
\end{cases}$$

The energy conservation $U^2 + (1 + T_k) V^2 = 2E_q/\left( mb^2 \right)$ gives the orbits on the phase plane $(U, V)$, namely each point of the $U$-axis and the semi-ellipses $V = \pm \sqrt{E_q/\left( mb^2 \right) - U^2/2}\sqrt{1 + T_k}$. Moreover $\lim_{t \to +\infty} V(t) = 0$,

$$\lim_{t \to +\infty} U(t) = \pm \sqrt{2E_q/\left( mb^2 \right)},$$

that is $\psi(t) \to \text{constant}$, $B \to \text{constant}$.

Again for $h = 0$, the special case $B = P_0$, that concerns with one typical instance in nonholonomic constraints (see for instance [1]), cannot be recovered from the system of Remark 1.2, but it requires the definition of the pseudovelocity $U = \xi_0/\cos \psi$.

We are going now to investigate the stability of the system at $\theta = 0$.

For what concerns with the initial data, we can certainly assume with no loss in generality $\xi_0(0) = 0$, $\eta_0(0) = 0$, $\psi(0) = 0$, hence $q(0) = (bU(0), bV(0), V(0), W(0))$.

Let us first check whenever $\theta(t) \equiv 0$ is a solution of (7).

**Statement 1.2** $\theta(t) \equiv 0$ is solution of (7) if and only if $U$ is constant and $V = 0$.

**Proof.** Set $\theta = 0$ in (7), first three equations:

$$\begin{cases}
U = V^2 \\
(1 + T_k) V = -UV \\
V = -UV
\end{cases}$$

which entails $V = 0$, $U = U(0)$. We incidentally notice that if $T_k \ll 1$ then $U$, $V$ consistent with $\theta = 0$ are those we discussed in Remark 1.3.

On the other hand, $U$ constant and $V = 0$ make us write (12), second and third equation, as

$$W \cos \theta = W(0) \cos \theta(0), \left( T W^2 - \left( g\bar{h}/b \right) \cos \theta \right) \sin \theta = 0$$

(15)

(it is physically correct to assume $-\pi/2 < \theta(0) < \pi/2$), which implies $\theta(t) = 0$. □

**Remark 1.2** The following statement also follows from the previous analysis: if the angle $\psi$ is constant (that is $B - A$ never changes direction), then $U$ has to be constant and $\theta(t)$ has to be zero.

**Corollary 1.1** Assume $\theta(0) = 0$, $\dot{\theta}(0) = W(0) = 0$; then $\theta(t) = 0$ is solution of (7) if and only if $V(0) = 0$.

**Proof.** If $\theta = 0$ is solution, then $V$ must be zero at any time; on the other hand, the set of data $U(0) = U_0$, $V(0) = 0$, $\theta(0) = 0$, $W(0) = 0$ give univocally the solution $\theta(t) = 0$, $\theta(t) = U(t) = U_0$, $\theta(t) = 0$. □

Our aim points now to discuss the stability of $\theta(t) = 0$. There physical problem requires $U_0 > 0$ (see (5)). Incidentally we notice that if $\left( U(t), V(t), W(t), \theta(t) \right)$ is the solution of (7) starting from $\left( U_0, V_0, W_0, \theta_0 \right)$, then $\left( U(t), -V(t), -W(t), -\theta(t) \right)$ is the solution of the same equations corresponding to $\left( U_0, -V_0, -W_0, \theta_0 \right)$.

It may be helpful by the way to set $t = 0$ in (7) in order to figure out the behaviour of the solution for short
times:

\[ \dot{U}(0) = V_0^2, \quad \dot{V}(0) = -\frac{1-\kappa}{1-\kappa+T_k}U_0V_0, \quad \dot{W}(0) = \frac{T_k}{\kappa/h}U_0V_0 \]

that is, assuming for instance \( U_0 > 0, \ V_0 > 0, \) and \( U \) and \( W \) are initially increasing, \( V \) decreasing.

Let us now show the following

**Proposition 1.1** *The equilibrium point \( X_0 = (U_0, 0, 0, 0) \) of (12) is unstable.*

**Proof.** We set (12) in normal form: calling \( G(\theta) = \det \mathcal{A}/T \), where \( \det \mathcal{A} \) is computed in (13), it is easily found

\[
\mathcal{A}^{-1} = \frac{1}{G(\theta)} \begin{pmatrix}
1-\kappa+T_k+(\kappa+T_k)\sin^2 \theta & -\kappa \sin \theta & -\kappa \cos \theta \sin \theta & 0 \\
-\kappa \sin \theta & 1 & (\kappa/h) \cos \theta & 0 \\
-\kappa \cos \theta \sin \theta & (\kappa/h) \cos \theta & (1-\kappa) \sin^2 \theta + (1+T_k)/T & 0 \\
0 & 0 & 0 & G(\theta)
\end{pmatrix}
\]

so that \( F(X) = \mathcal{A}^{-1}(\theta) \mathcal{F}(X) \) can be calculated (see (12) for \( \mathcal{F} \)). We now compute the Jacobian matrix of \( F(X) \) at the equilibrium \( X_0 = (U_0, 0, 0, 0) \): calculations lead to

\[
J_X F(X_0) = \frac{1}{G(0)} \begin{pmatrix}
0 & 0 & 0 & 0 \\
-1-\kappa U_0 & 0 & g\kappa/b \\
T_k U_0 \kappa/h & 0 & (1+T_k) g\kappa/(b\kappa) \\
0 & 0 & G(0) & 0
\end{pmatrix}
\]

where \( G(0) = 1-\kappa+T_k > 0 \). The eigenvalues \( \sigma \) are found by solving

\[
\sigma(G(0)\sigma^3+(-1-\kappa)U_0\sigma^2-\gamma(1+T_k)\sigma-\gamma U_0) = 0, \quad \gamma = \frac{g\kappa}{b\kappa}.
\]

Since \( U_0 > 0 \), the polynomial \( \psi(\sigma) \) in brackets is such that \( \psi(0) < 0 \) and \( \lim_{\sigma \rightarrow +\infty} \psi(\sigma) = +\infty \), so that there exists one real and positive eigenvalue \( \sigma \) and standard results in this sense (see e.g. [8]) can be implemented. □

The linear approximation \( \dot{X} = J_X F(X_0) X \) entails \( \dot{U} = 0 \) and

\[
G(0)\dot{V} = -(1-\kappa)U_0\dot{V} + \kappa \gamma \theta, \quad G(0)\dot{W} = \frac{\kappa}{h}T_k U_0 V + \frac{g\kappa}{b} (1+T_k) \theta
\]

which give the equation for \( \theta \):

\[
G(0)\frac{d^2 \theta}{dt^2} + U_0 \kappa \dot{\theta} - \gamma (1+T_k) \dot{\theta} + U_0 \theta = 0
\]

which diverges the same.

An analytical investigation can be performed directly for system (7): choosing for instance, as it is natural, \( \dot{\theta}(0) = 0, \ W(0) = 0 \) and \( V_0 \neq 0 \), (16) shows that \( \theta \) initially increases, so that \( \theta \) enters the quarter \( (-V_0, j, e) \). Furthermore, setting \( Z = V \sin \theta, \ \psi(\theta) = 1-\kappa \cos^2 \theta + T_k + T_k \sin^2 \theta > 0 \) one writes (7) as

\[
\begin{align*}
\dot{U} &= \frac{1}{\psi(\theta)} \kappa U Z (1-\kappa \cos^2 \theta) + F_1 (V, W, \theta), \\
\dot{Z} &= -\frac{1}{\psi(\theta)} \kappa U Z (1-\kappa \cos^2 \theta) + F_2 (V, W, \theta)
\end{align*}
\]
with appropriate $F_1$, $F_2$; on the other hand, using also
\[
\frac{1}{2} \dot{b} b^2 \dot{W}^2 + gh (\cos \theta - 1) + G(U,V,W,\theta) = \frac{1}{2} \left( U_0^2 + (1 + T_0) V_0^2 \right)
\]
which is (11) with the appropriate $G$, one should acquire information about the maintenance of $U > 0$ ($A - B$ does not change verse), of $Z < 0$ (the transverse velocity of $O$ is opposite to the position of $P_0$ with respect to the vertical direction) and of $W > 0$ (absence of inversion with respect to $\theta$). Such as analysis will be not expanded, in order not to overload the Section.

**Remark 1.3** We have not imposed any constraint on the velocity of $A$ yet: the velocity $\dot{A}$ can be calculated a posteriori by means of (5) and the angle $\beta$ between $i$ and $\dot{A}$ is such that
\[
\cos \beta = \frac{U}{\sqrt{U^2 + (1 + \alpha)^2 V^2}}
\]
where $\alpha = a/b$.

**Remark 1.4** It is sometimes assumed in literature (more or less expressly) to know $U$ e $V$: in that case system (7) is obviously simpler, but such an assumption corresponds to impose the constraints $\dot{\lambda}_0 \cos \psi + \eta_0 \sin \psi = U$, $-\dot{\lambda}_0 \sin \psi + \eta_0 \cos \psi = V$, with given $U$ and $V$. Hence $(\dot{\lambda}_0 \cos \psi - \lambda_0 \sin \psi, \lambda_0 \sin \psi + \lambda_0 \cos \psi, 0, 0)$ must appear on the right-hand side of (3), with $\lambda_0$, $\lambda_0$ unknown multipliers. As a whole, we get seven equations in the seven unknown quantities $q_0$, $\lambda_0$, $\lambda_0$ and $\lambda_0$.

### 1.3. Adding a Stabilizing Device

Following the approach in [6], we add an external force in order to modify the dynamics of the system and to infer the stability of the stationary solution.

We impose a force $F_A = F_{\alpha} j_1$, in $A$, where $j_1 = e_z \wedge i$ (horizontal versor perpendicular to $B - A$) and $F = F + F^{(1)}(s)$ in $P_0$; we expect $f_1 = f_0(U,V,W,\theta)$, the same for the other coefficients. Notice that a force along $j_1$ in $B$ would have no effects.

Computing the Lagrangian components $F_\theta$ of the vector of forces in the tangent space and taking the projection $\Gamma^T F_\theta$ (see (6)), one can check that the term to add to the right-hand side of (7), first three equations, is
\[
\frac{1}{mb^2} \begin{pmatrix} 0 \\ (a + b) F_1 + b (f_1^{(1)} + F_1 \cos \theta) \\ -h (F_1 + F_1^{(1)} \cos \theta) \end{pmatrix}
\]

The conclusion of Statement 1.1 about existence and uniqueness is not altered, since the matrix $A$ of (12) is still the same.

Let us investigate about the effect of stabilization by the external device in the case of the force in $A$ only: $F_A = F^{(1)} = 0$ (actually the overlap of $F_A$ does not change the substance). Moreover, $F_A$ has to vanish at the equilibrium:
\[
a + b \frac{mb^2}{F_A} = f (U,V,W,\theta), f (U,0,0,0) = 0.
\]

It can be easily seen that the characteristic polynomial (17) changes into
\[
\sigma \left[ G(0) \sigma^3 - \left( \kappa - 1 \right) U_0 + \frac{\partial f}{\partial \nu} + \kappa \frac{\partial f}{\partial W} \sigma^2 - \left( \kappa \frac{\partial f}{\partial W} U_0 + \frac{\partial f}{\partial \theta} \sigma \right) + \gamma (1 + T_0) \sigma \right]
\]
\[
- \left( \gamma \left( U_0 - \frac{\partial f}{\partial \nu} \right) + \frac{\kappa \partial f}{\partial \theta} U_0 \right) = 0
\]
where the partial derivatives are calculated in $X_0 = (U_0, 0, 0, 0)$. The following Proposition sets a selection of choices for $f$.

**Proposition 1.2** (o) If $a_0 > 0$ then the system is unstable.

1) for $a_0 < 0$:
   a) if $a_1 \geq 0$ or $a_2 \geq 0$ then the system is unstable,
   b) if $a_1 < 0$ and $a_2 < 0$ and $a_1a_2 < -G(0)a_0$ [resp. $a_1a_2 > -G(0)a_0$], then the system is unstable [resp. stable].

2) For $a_0 = 0$:
   c) if $a_1 > 0$ or $a_2 > 0$, then the system is unstable,
   d) if $a_1 \leq 0$ and $a_2 \leq 0$, then the (real or complex) eigenvalues different from zero have negative real part.

**Proof.**

1) a) If $0 < a < 0$ then the system is unstable.

b) If $a_1 \geq 0$ or $a_2 \geq 0$, then the system is unstable. Likewise, if $a_1 \geq 0$, then it must be $b_1 < 0$ and we conclude in the same way.

b) It has to be checked the sign of $b_1$: from (22) we see that $b_1$ must solve

$$b_1^2 + a_2b_1 - G(0)a_1 = \frac{G^2(0)a_0}{a_2 + b_1}.$$

The latter equation has a unique positive [resp. negative] solution $b_1$ if and only if $a_1a_2 > -G(0)a_0$ [resp. $a_1a_2 < -G(0)a_0$]. For $b_1 < 0$ we conclude as before; on the other hand, if $b_1 > 0$ the real part of the (real or complex) solutions of $\sigma^2 + b_1\sigma + b_0 = 0$ is negative.

2) c) If $a_0 = 0$ then $p(0) = 0$. The rest of the eigenvalues are the roots of $G(0)\sigma^2 - a_1\sigma - a_0 = 0$. If $a_1 > 0$ then a real positive root exists, while if $a_1 > 0$ then either a real positive eigenvalue exists or the real part of the complex roots is positive.

d) In that case the eigenvalues are 0 (twice) and the two roots of $G(0)\sigma^2 - a_1\sigma - a_0 = 0$, which are nonpositive if real or with nonpositive real parts if complex. □

The linear approximation $X = J\dot{X}(X_0)X$ of (7) with the “new” $F$ encompassing the external force $f_u$ is $U = 0$ and

$$
G(0)\dot{V} = \left(\frac{\partial F}{\partial V} - (1 - \kappa)U_0\right)V + \frac{\partial F}{\partial W}W + \left(1 + \frac{\partial F}{\partial \theta} + \gamma\right)h\theta,
$$

$$
G(0)\dot{W} = \kappa\left(\frac{\partial F}{\partial V} + U_0\dot{T}_k\right)V + \frac{\partial F}{\partial W}W + \left(\frac{\partial F}{\partial \theta} + \frac{\partial F}{\partial \theta} + \frac{g}{b}(1 + \dot{T}_k)\right)\theta
$$

which generalizes (18). The partial derivatives are calculated at the equilibrium $(U_0, 0, 0, 0)$. The equation for $\theta$ replacing (19) is

$$
G(0)\frac{d^2\theta}{dt^2} = -a_2\ddot{\theta} - a_1\dot{\theta} - a_0\theta = 0
$$

(see (21) for the definition of $a_2$, $a_1$, $a_0$). Hence the stable case 1), b) in Proposition 1.2 is asymptotic stability for $\dot{\theta}$. Case 2), d) concerns with $G(0)\dot{W} - a_2\dot{W} - a_0W = 0$ so that $\sigma_{1,2} = \frac{-a_2 \pm \sqrt{a_2^2 - 4a_1}}{2}$. (real or complex) and (assume $\Delta = a_2^2 - 4a_1 \neq 0$)

$$
W(t) = \frac{1}{\Delta}e^{-a_2t/2}\left((\dot{W}_0 - \sigma_2W_0)e^{\sigma_2t/2} + (\sigma_1W_0 - \dot{W}_0)e^{-\sigma_1t/2}\right)
$$
where \( \dot{\mathbf{H}}_0 \) comes from (23), second equation. Obviously each specific case (coincident eigenvalues, \( a_1 \) or \( a_2 \) equal to zero, ...) can be examined deeper.

**Remark 1.5** A simple guess for \( f \) is \( f = \alpha UV + \alpha W \), with \( a_1 \) and \( a_2 \) constant; in that case \( a_1 < 1 \) or \( a_2 \geq 0 \) gives instability. The stability region located by case 1), b) in the quarter \( (a_1 > 1, a_2 < 0) \) is not empty: actually, \( a_1 < 0 \) and \( a_2 < 0 \) corresponds to the set \( 0 < a_1 - 1 - \kappa \left( 1 + a_2 \left( \frac{\mathbf{H}}{\mathbf{U}_0} \right) \right) \), possibly cut on the upper part by the line \( a_2 = - \left( 1 + T_k \right) g / (\mathbf{H} \mathbf{U}_0) \), if the latter value is lower than \( - \mathbf{H} / \mathbf{U}_0 \). Such a set has a nonempty intersection with \( a_1 a_2 > - G(0) a_0 \): indeed, it is sufficient to take, for each fixed \( a_1 > 1 \), \( a_2 \) large enough in module.

Furthermore, the case 2), d) is simply \( (20) \). Inversely, the achieved conditions can be also read in terms of finding \( \dot{\mathbf{U}}_0 \), for a given external force \( f_0 \) as in (20), in order to get stability. In particular, the case \( a_1 = 1 \) studied in [6] concerns with a counterbalance effect, so that the term \( UV \) in (7), second equation, vanishes.

**Remark 1.6** The simplifying assumption \( \dot{\mathbf{U}} = 0 \) sometimes used in models makes sense only around the equilibrium position: far from \( \mathbf{X}_0 \), the linear approximation \( \dot{\mathbf{U}} \) constant would force the system to non reasonable predictions. Besides that, the same assumption is not a consequence of the equations, as we pointed out in Remark 1.1.

### 2. A Two-Body Model

#### 2.1. The Equations of Motion

We now consider a rigid device simulating the front wheel, adding to the body \( \mathcal{A} \) a rigid part \( \mathcal{B} \) (say the front wheel together with handlebars) hung in \( \mathcal{A} \) and forming the angle \( \beta \) (front steering) between the direction \( i \) and a direction fixed in the body frame \( \mathcal{B} \):

\[
\mathbf{e}_\beta = \cos \beta \mathbf{i} + \sin \beta \mathbf{j}, \quad \mathbf{j} = \mathbf{e}_\beta \wedge \mathbf{e}_z = - \sin \psi \mathbf{e}_1 + \cos \psi \mathbf{e}_2.
\]

For the sake of simplicity, we may imagine \( \mathcal{B} \) as a rigid bar laying on \( z = 0 \), with no active force operating on it. We now consider the five lagrangian coordinates \( q = (\xi, \eta, \psi, \theta, \beta) \). The angular velocity of \( \mathcal{A} \) is hence \( \omega_{\mathcal{A}} = (\dot{\psi} + \dot{\beta}) \mathbf{e}_\beta \).

The Lagrangian function of the whole system is \( \mathcal{L} = \mathcal{L} + \mathcal{T}_{\mathcal{A}}, \) where \( \mathcal{L} \) is the same as (1) and

\[
\mathcal{T}_{\mathcal{A}} = \frac{1}{2} m_{\mathcal{A}} \dot{\mathbf{A}}^2 + \frac{1}{2} \omega_{\mathcal{A}} \cdot \sigma(A) \omega_{\mathcal{A}}
\]

\[
= \frac{1}{2} m_{\mathcal{A}} \left( \dot{\xi}^2 + \dot{\eta}^2 + \dot{\theta}^2 + 2 \dot{\psi} \dot{\theta} + 2 \dot{\psi} \dot{\theta} + 2 \dot{\psi} \dot{\theta} + 2 \dot{\psi} \dot{\theta} + 2 \dot{\psi} \dot{\theta} \right)
\]

where \( \beta \) is a new lagrangian coordinate and \( m_{\mathcal{A}} \) and \( I_{\mathcal{A}} \) are respectively the mass of \( \mathcal{A} \) and the central inertial momentum of \( \mathcal{A} \) with respect to the direction \( \mathbf{e}_3 \). The equation of motion with respect to \( \beta \) is simply

\[
I_{\mathcal{A}} \left( \ddot{\beta} + \dot{\psi} \right) = 0.
\]

Equation (24) gives

\[
\dot{\beta}(t) = (\dot{\beta}(0) + \dot{\psi}(0)) t + \dot{\beta}(0)
\]

where \( \dot{\beta} = \beta + \dot{\psi} \) is the angle between \( \mathbf{e}_1 \) and \( \mathcal{A} \).

**Remark 2.1** If no further constraints are enjoined, the system is unstable the same: actually, changements in (7) are not essential: still keeping \( \mathbf{X} = (U, V, W, \theta), \quad \mathbf{X}_0 = (U_0, 0, 0, 0) \) is again an equilibrium point for the system \( A_\mu(\theta) \mathbf{X} = \mathcal{F}_\mu(\mathbf{X}), \) where

\[
A_\mu(\theta) = \begin{pmatrix}
1 + \mu & \frac{\mathbf{H}}{\mathbf{U}_0} \sin \theta & 0 & 0 \\
\frac{\mathbf{H}}{\mathbf{U}_0} \sin \theta & 1 + T_k + T \sin^2 \theta + \mu (1 + \alpha_1) \frac{\mathbf{H}}{\mathbf{U}_0} \cos \theta & - \frac{\mathbf{H}}{\mathbf{U}_0} \cos \theta & 0 \\
0 & - \frac{\mathbf{H}}{\mathbf{U}_0} \cos \theta & \frac{\mathbf{H}}{\mathbf{U}_0} & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\]
\[ F_\mu (X) = \begin{cases} 
V (1 + \mu(1+\pi)) V - 2\bar{h}W \cos \theta 
\downarrow 
(1 + \mu(1+\pi)) U V - W \sin \theta (\bar{h}W + 2TV \cos \theta) 
\downarrow 
V \cos \theta (TV \sin \theta + \bar{h}U) + (g\bar{h}/b) \sin \theta 
\downarrow 
W 
\end{cases} \]

and (13), (17) are replaced respectively by

\[ \text{det} A_\mu (\theta) = T \left[ 1 - \kappa + \bar{t}_k + (1 - (\kappa/(1+\mu)) + (\kappa/T)) T \sin^2 \theta + \mu(1+\bar{\alpha})^2 \right] = \bar{R} \mu (\theta) > 0 \]

\[ \sigma (G_\mu (0) \sigma^2 + (1 + \mu)U_o (1 - \kappa + \bar{t}_k + \bar{\alpha}) \sigma^2 - \gamma (1 + \mu)(1 + \bar{t}_k + \bar{\alpha}(1 + \bar{\alpha})) \sigma \]

\[ (-\gamma (1 + \mu)^2) [G_\mu (0) + \bar{\alpha} (1 - \kappa + \bar{t}_k + \bar{\alpha})] U_o / G_\mu (0) = 0 \]

\[ \bar{\alpha} = \mu(1+\bar{\alpha}) \]

which has in the same way one real positive solution.

We now add the kinetic constraint of no skidding of \( \mathbb{A} \) at \( A \): \( \dot{A} \wedge e_\beta = 0 \) which gives

\[ \ddot{x}_0 \sin (\beta + \psi) - \dot{\eta}_0 \cos (\beta + \psi) - a \dot{\psi} \cos \beta = 0. \quad (25) \]

A possible way to face the problem is to neglect the mass \( m_\mathbb{A} \) of the anterior part, so that the Lagrangian function is the same as (1). However, a complication is, in our point of view, the role of \( \beta \), which does not appear in \( \mathcal{L} \), but only in the constraint (25).

This is a nontrivial point for the theory-building of the correct equations of motion: the way we are going to follow is not to neglect the mass \( m_\mathbb{A} \) and consider \( \mathcal{L} \) as the Lagrangian function. Even more, if we think of the problem as a “bicycle” model, the front mass is not at all unsignificant for the overall frame.

We now consider the set of Lagrangian coordinates \( q = (\xi_0, \eta_0, \psi, \theta, \beta) \): system (3) of the first kind Lagrangian equations is now replaced by the seven equations

\[ \frac{d}{dt} \nabla_q \mathcal{L}_\xi - \nabla_q \mathcal{L}_q = \lambda_0 (\sin \psi, -\cos \psi, b, 0) + \lambda_2 (\sin (\psi + \beta), -\cos (\psi + \beta), -a \cos \beta, 0, 0) \]

\[ b \dot{\psi} + \ddot{x}_0 \sin \psi - \dot{\eta}_0 \cos \psi = 0, \]

\[ \ddot{\xi}_0 \sin (\beta + \psi) - \dot{\eta}_0 \cos (\beta + \psi) - a \dot{\psi} \cos \beta = 0. \quad (26) \]

where \( \xi_0, \eta_0, \psi, \theta, \beta, \lambda_0 \) and \( \lambda_2 \) are the seven unknown quantities. Concerning with the initial conditions for (26) we can choose, with no loss in generality:

\[ \xi_0 (0) = 0, \quad \eta_0 (0) = 0, \quad \psi (0) = 0, \quad \theta (0) = 0, \quad \beta (0) = \beta_0 \in (-\pi/2, \pi/2). \]

Let us change for the sake of convenience \( \beta \) into the variable

\[ y = \frac{\tan \beta}{1 + \bar{\alpha}} \]

so that \( \dot{\beta} = \frac{y^2}{1 + \bar{\alpha}} \dot{y} \). The velocities \( \dot{q} \) are not independent, because of (2), (25): if on the one hand

\[ \dot{\theta} (0) = \dot{\theta}_0 \quad \text{and} \quad \dot{\beta} (0) = \dot{\beta}_0 \quad \text{are arbitrary,} \]

on the other hand once \( \ddot{x}_0 (0) \) has been fixed the initial velocities

\[ \dot{\eta}_0 (0) = y (0) \ddot{x}_0 (0), \]

\[ \dot{\psi} (0) = y (0) \ddot{x}_0 (0) / b \]

are imposed. In order to reduce (26) and eliminate the multipliers, we define, similarly to (4), the pseudovelocities
Joining (29) with (2) and (25), the lagrangian velocities \( \dot{\mathbf{q}} \) are written in terms of the parameters \((U, W, Y)\):

\[
\begin{pmatrix}
\dot{\xi}_o \\
\dot{\eta}_o \\
\dot{\psi} \\
\dot{\theta} \\
\dot{y}
\end{pmatrix}
=
\begin{pmatrix}
b \cos \psi - y \sin \psi & 0 & 0 & 0 \\
\sin \psi + y \cos \psi & 0 & 0 & 0 \\
y & 0 & 0 & 1 \\
0 & 1 & 0 & 0 \\
-y \rho(y) & 0 & \rho(y) & 0
\end{pmatrix}
\begin{pmatrix}
\xi_o \\
\eta_o \\
\psi \\
\theta \\
y
\end{pmatrix}
\]

where \( \rho(y) = \frac{1 + (1 + \alpha)^2}{1 + \alpha} \) and, we recall, \( \alpha = a/b \).

The equations of motion replacing (7) are now

\[
\Gamma^T \left( \frac{d}{dt} \left[ \nabla_q \mathcal{L}_i - \nabla_y \mathcal{L}_i \right] \right) = 0, \quad \mathbf{q} = (\xi_o, \eta_o, \psi, \theta, \beta)
\]

together with (2), (25) and (29): straightforward computations lead to

\[
\begin{align*}
\dot{\xi}_o &= b \left( \cos \psi - y \sin \psi \right) U, \\
\dot{\eta}_o &= b \left( \sin \psi + y \cos \psi \right) U, \\
\dot{\psi} &= \dot{y} = \rho(y)(Y - Uy), \\
\dot{\theta} &= W, \\
\dot{y} &= -\rho(y)(Y - Uy), \\
\end{align*}
\]

(31)

where

\[
c = (1 + \mu)/\kappa, \quad \mathcal{T} = \mathcal{H}/\kappa = \mathcal{T}/\kappa, \quad \tau(\theta) = \left(1 + \mathcal{T} \sin^2 \theta + \mathcal{T}_k + \mu(1 + \alpha)^2 \right)/\mathcal{H}
\]

(32)

and, as before, \( \mu = m_m/m \), \( \alpha = a/b \), \( \kappa = h/b \), \( \mathcal{T} = I/mb^2 \), \( \mathcal{T}_k = I_k/mb^2 \).

Even in this case the equations of motion can be led back to the cardinal equations: indeed, calling \( \mathbb{P} \) the rigid part containing \( A, B \) and \( P_o \) (30), the second cardinal equation of the whole system \( \mathbb{P} \cup \mathbb{A} \) using \( B \) for calculating the momenta and projecting along \( e_i \) writes

\[
\left( \mathbf{\dot{L}}_p (B) + \mathbf{\dot{L}}_a (B) + \mathbf{\dot{L}}_m (B) \right) \cdot e_i = \mathbf{M}^{(i)} (B) \cdot e_i
\]

(33)

where \( \mathbf{M}^{(i)} \) is the momentum of the external forces of the whole system. Since the constraints are smooth, the force in \( A \) realizing the kinetic constraint (25) can be modelled as

\[
\Phi_{_{i}a}^{(i)} = \phi_{_{i}a}^{(i)} (-\sin \beta i + \cos \beta j)
\]

so that (see also (10)) \( \mathbf{M}^{(i)} (B) \cdot e_i = (a + b) \phi_{_{i}a}^{(i)} \cos \beta \). On the other hand, the first cardinal equation for the whole system along \( i \) is

\[
-\phi_{_{i}a}^{(i)} \sin \beta = m \mathbf{\dot{P}}_o + m \mathbf{\dot{A}}.
\]

Carring out all the computations, here omitted, one gets exactly (33). The second equation in (30) is again ascribable to the momentum balance of the system along \( i \), similarly to what discussed in Remark 1.1:

\[
\left( \mathbf{\dot{L}}_p (O) + \mathbf{\dot{L}}_a (O) + \mathbf{\dot{L}}_m (O) \right) \cdot i = \mathbf{M}^{(i)} (O) \cdot i = mgh \sin \theta.
\]
Finally, the fourth equation in (30), namely (24), is simply the second cardinal equation written only for $A$, and with respect to the point $A$, where all the momenta of the external forces vanish.

As we already remarked in Section 1, the overview of the system in the frame of the cardinal equations does not determine any conserved quantity: the only evident one is the energy conservation

$$
\frac{1}{2} \left[ (1 + \mu) + 2mT \right] U^2 + \frac{1}{2} T^2 + \frac{1}{2} Y^2 + \mu U T^2 \right] \right] + \mu U T^2 \right) \right] \right] + \mu U T^2 \right) \right] \right] + \mu U T^2 \right) \right] \right]
$$

### 2.2. The Mathematical Problem

System (30), (31) consists of eight ODEs for the eight variables $\xi, \eta, \psi, \theta, y, U, W, Y$. The five equations (30) form a sub-system for $(U, W, \theta, y, Y)$ together with the initial conditions

$$
U(0) = \xi(0) + b = U_0, \quad W(0) = \dot{\theta}_0, \quad \theta(0) = \theta_0, \quad y(0) = \frac{tg\beta_0}{1 + a} = y_0,
$$

while the constant value $Y$ is deduced from (24), (27) and (28):

$$
Y = \beta_0 + U_0 y_0 = \frac{1}{\rho(y_0)} \dot{y}(0) + U_0 y_0.
$$

Once (30) has been solved, (31) and (28) allow to solve $\xi, \eta, \psi, \theta$.

As in the case of Section 1, we incidentally remark that, if $(U, W, \theta, y, Y)$ as in (35) is solution of (30), then $(U, -W, -\theta, -y, Y)$ is solution of the same system, as we expect.

**Statement 2.1** For any set of data (34), (35) system (30) admits one solution.

**Proof.** System (30) can be concisely written as

$$
\begin{bmatrix}
A_1(x, y) \dot{X} = F_1(X, Y) \\
\dot{Y} = 0
\end{bmatrix}
$$

with $X = (U, W, \theta, y)$ and

$$
A_1 = \begin{bmatrix}
c + y(2 \sin \theta + y \tau(\theta)) & -y \cos \theta & 0 & 0 \\
-y \cos \theta & \mathcal{I} & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
$$

$$
F_1(X, Y) = \begin{bmatrix}
-c + y(2 \sin \theta + y \tau(\theta)) & y \cos \theta & 0 & 0 \\
-y \cos \theta & \mathcal{I} & 0 & 0 \\
0 & 0 & G_1 & 0 \\
0 & 0 & 0 & G_1
\end{bmatrix}
$$

the normal form being $X = A^{-1}_1(\theta, y) F_1(X, Y) = F_1(X, Y)$ with

$$
A^{-1}_1(\theta, y) = \frac{1}{G_1(\theta, y)} \begin{bmatrix}
\mathcal{I} & y \cos \theta & 0 & 0 \\
y \cos \theta & c + y(2 \sin \theta + y \tau(\theta)) & 0 & 0 \\
0 & 0 & G_1 & 0 \\
0 & 0 & 0 & G_1
\end{bmatrix}
$$

and

$$
G_1(\theta, y) = \det A_1 = \mathcal{I} \left[ c + y(2 \sin \theta + y \tau(\theta)) \right] - y^2 \cos^2 \theta
$$

$$
= \frac{1}{\kappa} \left[ \mu \left( 1 + \frac{1}{\kappa} \right)^2 + \left( 1 + \frac{\mu \sin \theta}{\kappa} \right)^2 + \left( 1 - \frac{\mu}{\kappa + \mu} \right)^2 + \left( \frac{\mu}{\kappa + \mu} + \frac{\mu}{\kappa} \right) \right] > 0. \quad \square
$$

It is evident that the unique solution of (30) corresponding to the initial data $U(0) = U_0, \quad W(0) = 0,
\[ \theta(0) = 0, \ Y(0) = 0, \ U \equiv U_0 \] and \( W \), \( \theta \), \( y \) identically zero. We notice that no other solutions such that the plane \( \text{ABP} \) is vertical are possible:

**Statement 2.2** If \( \theta(t) = 0 \), then \( U(t) = U_0, \ y(t) = 0, \ Y = 0 \). Conversely, if \( \theta(0) = 0, \ W(0) = 0 \) and \( U(t) = U_0, \ y(t) = 0, \ Y = 0 \), then \( \theta(t) = 0 \).

**Proof.** Set \( \theta = 0 \) in (30) and call \( \tau = 0 \):

\[
\begin{align*}
(1+c_0 y^2) \dot{U} &= -c_0 y U \rho(y)(Y - U) = -c_0 U y \rho(y), \\
-\dot{y} U &= U \left[ U y + \rho(y)(Y - U y) \right] = U (U y + y) \\
\dot{y} &= \rho(y)(Y - U y),
\end{align*}
\]

The first two equations give \( U = U_0 \sqrt{1 + c_0 y^2} / (1 + c_0 y_0^2) \); on the other hand, eliminating \( \dot{y} \) from second and third equations yields

\[
\frac{1 - (1+c_0 y^2)}{\rho(y)} U y = U_0 y_0 \rho(-1 + (1+c_0 y_0^2) / \rho(y_0)),
\]

hence \( y = y_0 \) and \( U \equiv U_0 \). But \( y_0 \) is consistent with the second equation only if \( y_0 = 0 \) and the third equation leads to \( Y = 0 \).

Conversely, if \( U = U_0, \ y = 0, \ Y = 0 \) are replaced in (30), one gets \( TW = (g/b) \sin \theta \) that, together with the initial conditions, gives \( \theta = 0 \).

Still concerning with the initial data assignment, we notice that if \( \dot{\beta}_0 = 0 \) (which is a reasonable condition for \( t = 0 \) we get from (35) \( Y = U_0 y_0 \); we wonder whether solutions such that \( U_0 \equiv U_0 y_0 \) (meaning \( \beta = 0 \) and \( \psi \equiv Y \) constant) are possible. From (30), fourth equation, one gets \( y = y_0 \), \( U \equiv U_0 \). If \( y_0 = 0 \) we clearly have \( \beta = 0, \ \psi = Y \) and \( TW = (g/b) \sin \theta \), for \( \theta(t) \). If on the other hand \( y_0 \neq 0 \), by replacing \( U_0 \) and \( y_0 \) in the first two equations of (30) we achieve the first integrals

\[
W \cos \theta - U_0 \sin \theta (2 + Y_0 \sin \theta) = W(0) + \frac{T}{2} U_0 y_0,
\]

\[
TW^2 - U_0 y_0 W \cos \theta - \frac{2g}{b} (1 - \cos \theta) = TW^2(0) - U_0 y_0 W(0)
\]

so that only \( \theta = \theta_0, \ W = 0 \) can be a solution. Substituting in the first integrals we see that \( \theta_0 = 0, \ y_0 = 0 \), that is the stationary solution.

We are going to investigate the stability of the stationary solution.

**Proposition 2.1** The equilibrium point \( X_0 = (U_0, 0, 0, 0), \ Y = 0 \) of (36) is unstable.

**Proof.** The Jacobian matrix at the equilibrium is

\[
J_{(x,y)}(F_1(x,y),0) = \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & g/(b \pi) & \pi U_0^2 / ((1+\pi) \pi) & U_0 / ((1+\pi) \pi) \\
0 & 1 & 0 & 0 \\
0 & 0 & -U_0 / (1+\pi) & 1 / (1+\pi) \\
0 & 0 & 0 & 0
\end{bmatrix}
\]

whose eigenvalues are \( 0, \ -U_0 / (1+\pi), \ \pm \sqrt{g/(b \pi)} \). The linearized system

\[
\begin{align*}
\dot{U} &= 0 \\
\pi \dot{\theta} - (g/b) \theta &= (\pi U_0 y + Y) U_0 / (1+\pi) \\
(1+\pi) \dot{y} + U_0 y &= Y \\
\dot{Y} &= 0
\end{align*}
\]

gives

\[
U \equiv U_0, \ \ Y = \dot{\beta}_0 + U_0 y_0, \ y(t) = y_0 + \frac{Y}{U_0} \left( 1 - e^{-U_0 t / (1+\pi)} \right),
\]

\[
\theta(t) = \frac{1}{2} \left( \theta_0 + W_0 \sqrt{b \pi / g} \right) e^{\pi U_0 y_0 / \sqrt{g/(b \pi)}} + \left( \theta_0 - W_0 \sqrt{b \pi / g} \right) e^{-\pi U_0 y_0 / \sqrt{g/(b \pi)}} + C_1 + C_2 e^{-\eta t}
\]

\[\Box\]
with \( u_0 = U_0/(1+\alpha) \), \( C_1 = \frac{bu_0}{g}(1+\alpha)Y + \alpha U_0 y_0 \), \( C_2 = \frac{-\alpha YU_0}{Iu_0^2 -(g/b)} \). □

We remark that, as bigger is \( \mathcal{I} = I/\mathcal{H} \) as longer is the time when the planar body \( ABP_0 \) falls to the ground \( (\theta = \pi/2) \).

3. Discussing Some Specific Assumptions

It is evident that the stability of the system can be achieved by introducing an external force as in Paragraph 1.3: instead of replay such a theme, we prefer to discuss some assumptions recurring in literature which indeed simplify the mathematical problem.

First of all, let us see what happens if we let \( U = U_0 \), known constant. If \( \beta_0 = 0 \) then \( Y = U_0 y_0 \) and the solution is \( y(t) = y_0 \) (that is \( \beta(t) = \beta_0 \)) and \( \psi(t) = \psi_0 t \). The point \((\xi_0, \eta_0)\) draws the circle \( (\xi_0 + b)^2 + (\eta_0 - b/y_0)^2 = (b/y_0)^2(1+y_0^2) \), \( y_0 = tg\beta/(1+\alpha) \).

On the other hand, if \( \beta_0 \neq 0 \), the angle \( \beta \) can be calculated by (30), fourth and fifth equations, regardless of the rest of the system:

\[
\frac{(1+\alpha)Y}{1+(1+\alpha)\beta Y} = 1, \quad Y = \beta_0 + u_0tg\beta_0, \quad u_0 = U_0/(1+\alpha).
\]

(37)

By integrating one gets in terms of \( \beta \):

\[
\frac{1+tg^{2}\beta(t)}{(Y-u_0tg\beta(t))}e^{2t(\beta(t)-\beta_0)} = \frac{1+tg^{2}\beta_0}{\beta_0^{2}}e^{2(\frac{u_0^2}{\beta_0^2})t}\beta_0 \quad \text{if} \quad Y \neq 0
\]

\[
tg^{2}\beta = \left(1+\frac{u_0^2}{\beta_0^2}\right)e^{2\alpha\psi} - 1 \quad \text{if} \quad Y = 0
\]

In any case, if (30) is accepted, the assumption \( U \) constant allows the immediate calculation of \( \beta \), irrespective of \( \theta \) and \( \psi \).

The same system (30) is worth considering together with the assumption, not uncommon in literature \[2\]-[11], \( \beta \propto \theta \). Actually, assuming \( \beta = \alpha \theta \), \( \alpha \) constant, would lead to the invariant quantity \( aW + Uy = Y \) and, by integration, \( \alpha(\theta - \theta_0) = Yt - \psi \). Hence also \( \psi \) is proportional to \( \theta \) and (30), second equation, can be written in terms of \( \theta \) only:

\[
(I + \alpha \cos \theta)W = (g/b)sin\theta + (Y - \alpha W)^2 \cos\theta \left( I \sin \theta + \frac{1+\alpha}{\tan \alpha \theta} \right)
\]

On the other hand, also (30), first equation, turns out to be written in terms of \( \theta \), since \( (1+\alpha)Y = \tan(\alpha \theta) \) and \( U = (Y - \alpha W)/Y \) : it should be checked that two obtained equations show compatibility.

Hence, in our mind the angle \( \beta \) also must be governed by the equations of motion which do not make room for an assumption such as \( \beta \propto \theta \).

Nevertheless, assume that the mass of \( \mathcal{A} \) is negligible, so that \( \mu \ll 1 \) and \( \mathcal{L}_c = \mathcal{L} \), as it is found in some models: in that case fourth and fifth equations in (30) have to be disregarded and \( \beta \) cannot longer be computed by means of (37). Following this point of view, the system is not closed, since \( \beta \) enters only the constraint condition (25) and not in the Lagrangian function \( \mathcal{L} \). This is the reason why an additional condition (say a constitutive law) is needed, as for instance \( \beta \propto \theta \).
