ABSTRACT

Background: Mycosis Fungoides (MF) is the most common and indolent form of Cutaneous T-cell Lymphomas (CTCL), that usually occurs in old adults. Objectives: To determine epidemiologic features and patients characteristics of MF in Isfahan (Iran). Methods: We performed a retrospective study in MF clinic of alzahra hospital that is the main center for treatment of MF patients in Isfahan (Iran) and evaluated clinicopathologic features. Results: In 3 years 25 patients were referred to Alzahra MF clinic. 18 patients diagnosed as MF. Seven (38.9%) patients were male and 11 (61.1%) were female with male to female ratio of 1:1.57. The mean age of patients was 41.06 years. 88.9% of our patients were in stages IA and IB. Conclusion: Most of our patients presented in early stages that were similar to other studies, while male: female ratio is different from other studies.

Keywords: Mycosis Fungoides; Epidemiology; Clinical Features; Iran

1. Introduction

Mycosis Fungoides (MF) is a disease of lymphatic tissues with primary involvement of the skin and is the most common and indolent form of Cutaneous T-cell Lymphomas (CTCL), followed by Sezary Syndrome. Initially, MF presents as a round or ovoid, flat erythematous or eczematous patch lesion, with or without fine scales [1-3].

MF usually occurs in old adults, with a median age between 55 and 60 years and a 2:1 male to female ratio [4,5].

The diagnosis of MF in its patch or early plaque phase is often difficult, either because MF mimic other cutaneous disorders such as benign dermatoses or discordance between clinical and pathologic findings [6,7].

Etiology of MF is unknown, however some studies suggested a causative role of environmental exposure to chronic antigenic stimulation, but they have not been substantiated by subsequent studies [8-10].

MF is a relatively rare disease and there is no registration system for this disease in Iran and therefore there is not enough epidemiologic information about MF in our country. The aim of this study is to collect epidemiologic information as well as patient characteristics and clinicopathologic features of MF in our region, Isfahan, Iran.

Corresponding author.
lesions, lesion distribution, tumor stage as well as results of pathology and molecular biology studies.

Cases other than MF were excluded from the study and patient’s forms were reviewed.

After data collection statistical analysis was performed by SPSS software version 19.

3. Results

During 3 years 25 patients were referred to Alzahra MF clinic. After clinical, histological and molecular clonality reevaluation, 18 patients diagnosed as MF. Seven (38.9%) patients were male and 11 (61.1%) were female with male to female ratio of 1:1.57. The mean age of patients was 41.06 years (median, 34.5 years; range, 25 - 86; standard deviation (SD), 17.9), and that was 41 for male and 41.09 for female patients.

Seven (38.9%) patients presented with patch, one of them had hypopigmented patch, 3 (16.7%) with plaque, 6 (33.3%) had combination of patch and plaque and the disease in 2 (11.1%) patients were in tumor stage.

We performed T-cell receptor gene rearrangement studies for all patients. In patients were diagnosed as MF, 11 (61.1%) were positive & 7 (38.9%) were negative.

Using TNM classification system, 8 patients (44.4%) were in stage IA, 8 patients (44.4%) were in stage IB and 2 (11.1%) in IIB.

Exposure to radiation or chemicals, lesion distribution, pathologic and IHC results of patients are shown in Table 1. Twelve (66.66%) patients had no remarkable exposure to sunray or chemical agents.

Fourteen (77.8%) of the cases were married. Most of the patients (83.3%) had educational degree of diploma or less. 81.8% of women were housekeepers and most of men were workers (42.9%) and salesmen (28.6%).

Seven patients (38.9%) were from Flavarjan and suburb, a small city close to Isfahan, and 5 (27.8%) from Isfahan city.

4. Discussion

The current study represents a retrospective review of patients referred to Alzahra MF clinic in three years, including 18 patients confirmed as MF.

There is a male predominance in almost all of studies on CTCLs and MF with a male: female ratio of 1.30 to

IHC: Immunohistochemistry; TCR: T-cell receptor gamma gene rearrangement assay; ND: Non diagnostic.
Male to Female ratio was about 1.00 - 1.4:1 in studies performed in some cities of Iran (Mashhad, Tabriz and Tehran) [21-23]. In present study this ratio is 1:1.57 that is similar to our previous study on incidence rate of MF in Isfahan with male: Female ratio of 3:4 (1:1.33) [24]. These ratios are completely in contrast to other studies. This difference might be due to ethnic group diversity, however to identify the causes of this difference, studies with more patients should be done.

Although MF usually affect older adults with median age of more than 50 years [1,25,26], it was lower in study in Singapore (33 years) [27]. The mean age of patients in a study in Kuwait was 35.2 years [28]. Their results are similar to our study with median of 34.5 years. It seems the age of disease presentation in Asian countries is lower, in contrast to western studies.

Approximately 80% of MF patients present in early stages (IA, IB and IIA) [15,20,29]. In agreement to other studies, 88.9% of our patients were in stages IA and IB.

T-cell clonality was present in about 70% (50% - 100%) of the biopsies diagnosed as MF [30-33]; this was 28.5% in a study in Hong Kong [20]. In current study 61.1% of cases showed clonality.

In present study high percentages of patients (38.9%) were from an agricultural area near to Isfahan (Flavarjan). A reason for this could be closeness of this city to Isfahan, so they can come to Isfahan easily; another might be environmental pollution due to huge industries near that area because according to previous studies environmental exposure to chronic antigenic stimulation (e.g., industrial chemicals, metals, and herbicides/pesticides) may have a causative role [8,10,34].

Occupations involving sun exposure increases the risk of MF [35]; but in this study 66.66% of patients hadn’t had remarkable exposure to sun, radiations or chemicals, although we hadn’t detail history of the patients’ exposures.

In a study in the United States, CTCL incidence rate correlated with high physician density, family income and higher education that were related to more access to health care. They also found higher incidence rate of MF in blacks and concluded that immunogenetics or interaction of genetic susceptibility and the environment in CTCL, may have a role in MF incidence [18]. In our study majority of the patients were educated up to the high school degree and commonly were housekeepers (women) and workers or salesmen (men).

In conclusion most of our patients presented in early stages that were similar to other studies, while male: female ratio is different from other studies.
