Abstract

We consider a rating-based model for the term structure of credit risk spreads wherein the creditworthiness of the issuer is represented as a finite-state continuous time Markov process. This approach entails a progressive drift in credit quality towards default. A model of the economy is presented featuring stochastic transition probabilities; credit instruments are valued via an ultra-parabolic Hamilton-Jacobi system of equations discretized utilizing the method-of-lines finite difference method. Computations for a callable bond are presented demonstrating the efficiency of the method.

Keywords

Optimal Stopping, Failure Rate, Regime Switching, Credit Risk Spreads

1. Introduction

When pricing of credit instruments subject to default risk, market participants typically assume that default is unpredictable, using dynamics derived from rating information in order to take advantage of credit events (cf. [1]). Generally, they fall into a loose hierarchy known as reduced-form models. The most ubiquitous approach involving hazard rate models wherein default risk via unexpected events is modeled by a jump process. In this framework, credit-risky securities are priced as discounted expectation under the risk neutral probability measure with modified discount rate (cf. [2], [3]). Although conceptually simple and easy to implement, these models are limited by the appropriate calibration of the hazard rate process. More generally, spread modeling represents spreads directly and eliminates the need to make assumptions on recovery (cf. [4], [5]). Finally, rating based models consider the creditworthiness of the issuer to be a key state variable used to calibrate the risk-neutral hazard rate (cf. [6]-[8]). A progressive drift in credit quality toward default (an absorbing state) is
now allowed as opposed to a single jump to bankruptcy, as in many hazard rate models. Rating based models are particularly useful for the pricing of securities whose payoffs depend on the rating of the issuer.

In this paper, we consider a rating based regime switching model for the term-structure of credit risk spreads in continuous time (cf. [9], [10]). A unique feature of our model is the inclusion of stochastic transition probabilities. Credit instruments are then characterized as the solution to an ultraparabolic Hamilton-Jacobi system of equations for which we develop a methods-of-lines finite difference method. Computations are presented for a rating based callable bond which validates the applicability and efficiency of the method.

2. Model of the Economy

In this section, we introduce the dynamics of the risk-less and risky term structures of interest rates as well as the bankruptcy process. To this end, we assume the existence of a unique equivalent martingale measure such that all risk-less and risky zero-coupon bond prices are martingales after normalization by the money market account (cf. [11], [12]). Without loss of generality, we suppose a single risky zero-coupon bond price and continuous trading over a finite time interval \([0, T]\). We let \(\tilde{E}(t) = \{0 < t < T\}\) denote a continuous time Markov process on the regime (or états) space \(\mathbb{I}_m = \{0, 1, 2, \cdots, m\}\) with associated transition probabilities \(P_j(t) = Pr\{\tilde{E}(t + \Delta t) = j | \tilde{E}(t) = i\}\), for all \(\Delta t > 0\); it follows that

\[
0 \leq P_j \quad \text{and} \quad \sum_{j=0}^m P_j = 1, \tag{2.1}
\]

for \(i \in \mathbb{I}_m\). Let \(P(t) = (P_{00}, P_{10}, \cdots, P_{mm})\) represent the \(i^{th}\)-state transition distribution.

We define the transition probabilities as follows. The \(0^{th}\)-state we associate with default, in which case \(P_0(s) = (1, 0, \cdots, 0)\). For \(i = 1, 2, \cdots, m\), we define the \(i^{th}\)-state transition dynamics consistent with the non-negativity constraint in (2.1) such that \((j = 1, 2, \cdots, m - 1)\)

\[
dP_j(s) = \alpha_j \left(P_j - P_j\right) ds + \sigma_j \beta_j(P_j) dW_j(s), \tag{2.2a}
\]

\[
P_j(t) = p_j \in (0, 1), \tag{2.2b}
\]

for \(0 < t < s < T\), where

\[
\beta_j^*(P_j) = \begin{cases} 
P_j & \text{if } j < m-1 \\
1 - \sum_{i=0}^{m-1} P_i & \text{if } j = m-1
\end{cases}
\]

and \(0 < \overline{p}_j\) is the mean transition level satisfying \(\sum_{i=0}^{m-1} \overline{p}_i \leq 1\), \(0 \leq \alpha_j\) is the rate of reversion to the mean, \(0 \leq \sigma_j\) and \(dW_j\) is a Wiener process. From (2.1), it follows that \(P_{m0} = 1 - P_{00} - P_{10} - \cdots - P_{m-1}\) and so

\[
dP_m(s) = -\sum_{j=1}^{m-1} \alpha_j \left(P_j - P_j\right) ds - \sum_{j=1}^{m-1} \sigma_j \beta_j(P_j) dW_j(s), \tag{2.2c}
\]

\[
P_m(t) = p_m = 1 - \sum_{j=1}^{m-1} p_j \in (0, 1). \tag{2.2d}
\]

We relate the transition matrix \(\Pi = (P_j)\) to the regime dynamics via the infinitesimal generator \(\Lambda\),

\[
\Lambda = \lim_{h \to 0} \frac{\Pi(h) - I}{h},
\]

such that

\[
\frac{dP(s)}{ds} = P(s)\Lambda,
\]

for \(0 < t < s < T\), and

\[
P(t) = P.
\]
where \( \mathbf{P} = (P_0, P_1, \ldots, P_m) \) is the vector of probabilities \( P_j(s) = Pr\{E(s) = j\} \). Without loss of generality, we associate \( E(s) \) with the vector \( \mathbf{E}(s) = \{e_0, e_1, \ldots, e_m\} \), \( e_0 = (1,0,\ldots,0) \), \( e_i = (0,1,\ldots,0) \), \( \ldots \), \( e_m = (0,0,\ldots,1) \), subject to the dynamics
\[
\begin{align*}
\mathcal{E}(s) &= \mathcal{E}(s)\Delta s + d\mathbf{M}(s), \\
\mathcal{E}(t) &= e,
\end{align*}
\]
for \( 0 < t < s < \hat{T} \), where \( \mathbf{M}(s) \) is a martingale with respect to the filtration generated by \( \mathcal{E} \) and \( \mathbf{P}(s) = \mathbb{E}[\mathcal{E}(s)] \) ([13], Chap 4.8; [14], Part III, App. B; [15], Chap 8). In particular, the state of the system is known at inception such that \( e_i = \mathbb{E}[\mathcal{E}(t)] = \mathbf{P}(t) = \mathbf{P} \), for some \( i \in \mathbb{I}_m \).

We suppose that the risky interest rate \( R \) follows a state specific Cox-Ingersoll-Ross dynamic given by
\[
\begin{align*}
dR(s; \mathcal{E}) &= \alpha(s) \cdot (\bar{\mathcal{E}}(s) - R)ds + \sigma(s)\sqrt{R} \cdot dW(s), \\
R(t; e) &= r(e),
\end{align*}
\]
for \( 0 < t < s < \hat{T} \), with mean reversion level \( \bar{\mathcal{E}}(s) \) and rate of reversion to the mean \( \alpha(s) \), such that
\[
\begin{align*}
\mathcal{E}(t) &= e,
\end{align*}
\]
where \( dW \) is a Wiener process. In default \( \alpha(e_0) = \sigma(e_0) = 0 \), otherwise \( \alpha(e_i) = \alpha \) and \( \sigma(e_i) = \sigma \). The risky bond price \( \mathcal{B} \) associated with a maturity \( T \) satisfies
\[
\begin{align*}
\frac{d\mathcal{B}(s)}{ds} &= R(s; e) \mathcal{B}(s), \\
\mathcal{B}(t) &= b.
\end{align*}
\]
We consider the risk-less interest rate \( \rho \) to satisfy
\[
\begin{align*}
d\rho(s; \mathcal{E})ds &= 0, \\
\rho(t; e) &= \rho(e),
\end{align*}
\]
where in default \( \rho(e_0) = 0 \) for convenience, and \( \rho(e_i) = \rho \) otherwise.

For a given contract \( \psi \), we define the value function associated with the joint Markov ultradiffusion process (2.2)-(2.5) such that
\[
\begin{align*}
v(t, b, r, \pi, e) &= \mathbb{E} \left\{ \exp \left[ -\rho(e) \cdot (T - t) \right] \cdot \psi(T, B(T), R(T), \Pi(T), \mathcal{E}) \right\},
\end{align*}
\]
for \( 0 < t < T < \hat{T} \), where \( \pi = \{P_j\} \).

In particular, for a non-coupon paying bond \( \psi(T, e_0) = \delta \) and \( \psi(T, e_i) = 1 \) otherwise, where \( \delta \) is the default recovery rate, whereas for a callable bond \( \psi(T, b, e_0) = 0 \) and \( \psi(T, b, e_i) = \max\{b - E(e_i), 0\} \) otherwise, for some rating based exercise price \( E(e_i) \). Generalization of (2.6) and the subsequent analysis to include early exercise features follows routinely and will not be considered here.

### 3. Characterization

Letting \( \mathbf{v}(t, b, r, \pi, e) = v(t, b, r, \pi, e_0) \) and
\[
\mathbf{v}(t, \cdot) = (v_0(t, \cdot), v_1(t, \cdot), \ldots, v_m(t, \cdot))^T,
\]
we recover (2.6) succinctly as
\[
\begin{align*}
v(t, \cdot; e_i) &= e_i \cdot \mathbf{v}(t, \cdot),
\end{align*}
\]
for \( i \in \mathbb{I}_m \). By Itô’s rule, the value function (2.6) is characterized via (3.1) as the solution to the ultraparabolic Hamilton-Jacobi system of equations
\[
\begin{align*}
\frac{\partial v_0}{\partial t} &= 0, \\
v_0(T, x) &= \psi_0(T, x)
\end{align*}
\]
\[
\frac{\partial v_i}{\partial t} + rb \frac{\partial v_i}{\partial b} + A_i v_i + p_{i0} v_0 + (p_{i1} - 1)v_i + \cdots + p_{im} v_m = 0 \\
v_i(T,x) = \varphi_i(T,x) \\
\vdots \\
\frac{\partial v_m}{\partial t} + rb \frac{\partial v_m}{\partial b} + A_m v_m + p_{m0} v_0 + p_{m1} v_1 + \cdots + (p_{mn} - 1)v_m = 0 \\
v_m(T,x) = \varphi_m(T,x),
\]
where

\[
A_i v = \frac{1}{2} r \sigma_i^2 \frac{\partial^2 v}{\partial r^2} + \alpha_i (T-r) \frac{\partial v}{\partial r} + \frac{1}{2} \sum_{j=1}^{m} \beta_j (P_j) \sigma_j^2 \frac{\partial^2 v}{\partial p_j^2} \\
- \sum_{j=1}^{m} \alpha_j (P_j) \frac{\partial v}{\partial p_j} - \rho (e_x) v.
\]

Let \( t = (t,b) \in \mathbb{Q} = (0,T) \times (0,1) \) denote the temporal variable and \( x = (r,p_1,p_2,\cdots,p_m) \in \Omega = (0,1)^m \times \{ \text{sum } p_j \leq 1 \} \times \cdots \times \{ \text{sum } p_m \leq 1 \} \) the spatial, we define

\[
\mathcal{H} = \frac{\partial}{\partial t} + rb \frac{\partial}{\partial b}
\]
and \( \mathcal{A} = (A_1,A_2,\cdots,A_m) \), such that the above can be written

\[
\mathcal{H} v(t,x) + \mathcal{A} \cdot v(t,x) + (\Pi - I) \cdot v(t,x) = 0,
\]
for all \( (t,x) \in \mathcal{Q} \times \Omega \), subject to the terminal constraint

\[
v(T,\cdot) = \varphi(T,\cdot),
\]
for \( (b,\cdot) \in (0,1) \times \Omega \), where \( \varphi = (\varphi(\cdot,e_x),\varphi(\cdot,e_1),\cdots,\varphi(\cdot,e_m))^T \).

4. Approximation Solvability
Towards obtaining a constructive approximation of (3.2), we consider an exhaustive sequence of bounded open domains \( \{ \Omega_k \} \) such that \( \Omega_k \subset \Omega_{k+1} \) and \( \bigcup \Omega_k = \Omega \) as well as a sequence of monotonically increasing real numbers \( T_k \to \infty \), as \( k \to \infty \). Let \( \Omega_k = (0,T) \times (0,T_k) \) and \( \partial \Omega_k = \{T\times(0,T_k) \cup (0,T) \times \{T_k\} \} \), we seek \( v_k(t,x) \) satisfying

\[
\mathcal{H} v_k(t,x) + \mathcal{A} \cdot v_k(t,x) + (\Pi - I) \cdot v_k(t,x) = 0,
\]
for all \( (t,x) \in \Omega_k \times \partial \Omega_k \), subject to the boundary condition

\[
v_k(t,x) = \varphi_k(t,x),
\]
for \( (t,x) \in \Omega_k \times \partial \Omega_k \), and terminal constraint

\[
v_k(T,x) = \varphi_k(T,x),
\]
for \( (T,x) \in \partial \Omega_k \). As (3.2) is an infinite horizon problem in \( b \), we remark to the necessity of introducing the artificial terminal condition \( v_k = \varphi_k \) along the frontier \( (T,b) \in \{T\} \times (0,T_k) \) (cf. [16]). In particular, \( v_k(t,x) \to v(t,x) \) as \( k \to \infty \), on any compact subset of \( \Omega \), for any fixed \( t \in \mathbb{Q} \).

We next place (4.1) into standard form by setting \( \tau = T-t, \quad \zeta_k = T_k - b, \quad (\tau,\zeta_k) \), in which case

\[
u_k(T-\tau,T_k-b,\cdot) = v_k(t,b,\cdot).
\]
Equation (4.1) becomes
\[\mathcal{H}_k = \frac{\partial}{\partial \tau} + r(T_k - \varsigma_k) \frac{\partial}{\partial \varsigma_k},\]
for all \((\tau, x) \in \mathcal{Q} \times \Omega\), subject to the boundary condition
\[u_k(\tau, x) = \psi(\tau, x),\] (4.2a)
for \((\tau, x) \in \mathcal{Q} \times \partial \Omega\), and initial condition
\[u_k(\tau_0, x) = \psi(\tau_0, x),\] (4.2c)
where \((\tau_0, x) \in \partial \mathcal{Q}_{0,k} \times \Omega\), where \(\partial \mathcal{Q}_{0,k} = [0] \times (0, T) \cup (0, T) \times \{0\}\).

We consider the discretization of (4.2) by the backward Euler method temporally and central differencing in space. To this end, we introduce the temporal step sizes \((\delta_\tau, \delta_\varsigma) \in \mathbb{R}^2\) and mesh sizes \((N_\tau, N_\varsigma) \in \mathbb{N}^2\), such that \(T = \delta_\tau \cdot N_\tau\) and \(T_k = \delta_\varsigma \cdot N_\varsigma\). Spatially, we utilize the step sizes \((\delta_\tau, \delta_\rho) \in \mathbb{R}^2\) and mesh sizes \((M_\tau, M_\rho) \in \mathbb{N}^2\); we denote the value of \(u_k\) on the grid by
\[u_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} = u_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)}(\tau, x),\]
the difference quotients are then backward first order in time:
\[\nabla_{\tau} u_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} = \frac{1}{\delta_\tau} \left[ u_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} - u_k^{(v_1-1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} \right],\]
and central second-order in space:
\[\delta_\tau^2 \mu_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} = \frac{1}{\delta_\tau} \left[ \mu_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} - \mu_k^{(v_1+1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} \right] + \frac{1}{\delta_\tau} \left[ \mu_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} - \mu_k^{(v_1-1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} \right] + \frac{1}{\delta_\tau} \left[ \mu_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} - \mu_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} \right]
\]
and so forth, and
\[\delta_\varsigma \mu_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} = \frac{1}{2\delta_\varsigma} \left[ \mu_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} - \mu_k^{(v_1+1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} \right] + \frac{1}{2\delta_\varsigma} \left[ \mu_k^{(v_1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} - \mu_k^{(v_1-1, v_2, \ldots, v_m, \rho_1, \ldots, \rho_m)} \right]
\]
and so forth.

Given the above, we define the method-of-lines finite difference discretization of (4.2) such that
\[-\mathcal{H}_k u_k(\nu, \mu) + A_k \cdot u_k(\nu, \mu) + (\Pi - I) u_k(\nu, \mu) = 0,\] (4.3a)
for all \((\nu, \mu) \in \mathcal{Q}_\delta \times \Omega_{k,\delta}\), subject to the boundary condition...
\[ u_k(v, \mu) = \psi(t, x), \]  
\[ (\mathbf{v}, \mu) \in \Omega \times \partial \Omega \]  
and initial condition  
\[ u_0(v_0, \mu) = \psi(t_0, x), \]  
where  
\[ (\mathbf{v}, \mu) \in \partial \Omega \times \Omega, \quad \partial \Omega = \{0\} \times \left[ 0,1, \ldots, N_x \right] \cup \left[ 0,1, \ldots, N_y \right] \times \{0\}, \]  
\[ H_v \mu = H_0(\mathbf{v}, \mu) u = \nabla u + \rho(\mu) (T_k - c_{\mu2}) \nabla u, \]
\[ \dot{A}_k = A_k(\mathbf{v}, \mu) u = \frac{1}{2} \rho^{\mu} \delta_k^2 u + \alpha_k \left( \tau_k - \rho^{\mu} \right) \delta_k u + \frac{1}{2} \beta_k^2 (P_k) \delta_{ij} \delta_k^2 u \]
\[ + \cdots + \frac{1}{2} \beta_{n+1}^2 (P_{n+1}) \delta_{n+1}^2 \delta_k^2 u - \sum_{1 \leq j < n} \frac{1}{2} \beta_j^2 (P_j) \sigma_{n-1,j}^2 \delta_k^2 u \]
\[ + \alpha_{ij} (\bar{p}_{ij} - p_{ij}) \delta_k u + \cdots + \alpha_{m-1,m-1} \left( \bar{p}_{m-1,m-1} - p_{m-1,m-1} \right) \sigma_{m-1,m-1}^2 \delta_k^2 u \]
\[ - \sum_{1 \leq j \leq m} \alpha_{ij} (\bar{p}_{ij} - p_{ij}) \delta_k u - \rho(e_k) u, \]
and  
\[ A = \{A_1, A_2, \ldots, A_n\}. \]
We solve (4.3) utilizing the pseudo-code (cf. [16], [17]):
\[
\text{do} \quad v_1 = 1, \ldots, N_x \\
\text{do} \quad \eta_2 = 0, \ldots, N_y \\
\text{solve for} \quad u_k(\mathbf{v}, \mu) \text{ via (4.3)}. \]

5. Numerical Experiment

In this section, we present a representative computation for the valuation of a callable bond relative to three credit ratings:

\[ \mathcal{E}(t) = \begin{pmatrix} e_0 \\ e_1 \\ e_2 \end{pmatrix} \]

with expiry  \( T = 0.5 \). We suppose a solvent risk-free rate of return of \( \rho = 0.02 \). For simplicity, we will consider the following transition matrix:

\[ \Pi = \begin{pmatrix} 1.00 & 0.00 & 0.00 \\ 0.0 & 0.95 & 0.05 \\ P_{\text{def}} & 0.10 - P_{\text{def}} & 0.9 \end{pmatrix} \]
in which only the default probability \( P_{\text{def}} = P_{\text{def}} \) is stochastic.

For  \( 0 < t < s < T \), we have the economy:
\[
\begin{align*}
    dP_{\text{def}}(s) &= 0.01 \left( 0.05 - P_{\text{def}} \right) ds + 0.05 \sqrt{P_{\text{def}} \left( 0.10 - P_{\text{def}} \right)} dW_{\text{def}}(s); \quad P_{\text{def}}(t) = P_{\text{def}} \\
    dR(s; \mathcal{E}) &= \alpha(\mathcal{E}) \left( \bar{f}(\mathcal{E}) - R \right) ds + \sigma(\mathcal{E}) \sqrt{R} \cdot dW(s); \quad R(t; \mathcal{E}) = r(e), \\
    dB(s) &= B(s) \cdot dB(s); \quad B(t) = b, \quad b,
\end{align*}
\]
where
\[ \alpha(\mathcal{E}) = \begin{cases} 0 & \text{if } \mathcal{E} = e_0 \\ 0.010 & \text{if } \mathcal{E} = e_1; \quad \sigma(\mathcal{E}) = \begin{cases} 0.20 & \text{if } \mathcal{E} = e_1 \\ 0.005 & \text{if } \mathcal{E} = e_2 \end{cases} \end{cases} \]
and

\[ \tau(\mathcal{E}) = \begin{cases} 0 & \text{if } \mathcal{E} = \mathcal{E}_0 \\ 0.03 & \text{if } \mathcal{E} = \mathcal{E}_1 \\ 0.06 & \text{if } \mathcal{E} = \mathcal{E}_2 \end{cases} \]

Letting \( \Gamma_k = 1.5 \) and \( \Omega_k = [0.0,0.5] \times [0.0,0.10] \), the ultraparabolic Hamilton-Jacobi system of Equations (4.1) for the value function \( v(t,b,r,p_{\text{def}}) = (v_0, v_1, v_2) \) associated with the ultradiffusion (5.1) is then

\[ v_0(t,b,r,p_{\text{def}}) = 0 \quad (5.2) \]

for all \((t,b,r,p_{\text{def}}) \in [0,T] \times [0, \Gamma_k] \times \Omega_k\),

\[ \frac{\partial v_1}{\partial t} + rb \frac{\partial v_1}{\partial b} + \frac{1}{2} r \sigma^2 \frac{\partial^2 v_1}{\partial r^2} + \alpha_x (\tau_x - r) \frac{\partial v_1}{\partial r} + \frac{1}{2} p_{\text{def}} (0.1 - p_{\text{def}}) (0.05)^2 \frac{\partial^2 v_1}{\partial p_{\text{def}}^2} + 0.01(0.05 - p_{\text{def}}) \frac{\partial v_1}{\partial p_{\text{def}}} - 0.02 v_1 + (0.95 - 1)v_1 + 0.05v_2 = 0 \quad (5.3a) \]

for all \((t,b,r,p_{\text{def}}) \in (0,T) \times (0, \Gamma_k) \times \Omega_k\), such that

\[ v_1(t,b,r,p_{\text{def}}) = \max \{b - 0.70, 0\}, \quad (5.3b) \]

for \((t,b,r,p_{\text{def}}) \in (0,T) \times (0, \Gamma_k) \times \partial \Omega_k\) and

\[ v_1(T,b,r,p_{\text{def}}) = \max \{b - 0.70, 0\}, \quad (b,r,p_{\text{def}}) \in (0, \Gamma_k) \times \Omega_k \quad (5.3c) \]

and

\[ \frac{\partial v_2}{\partial t} + rb \frac{\partial v_2}{\partial b} + \frac{1}{2} r \sigma^2 \frac{\partial^2 v_2}{\partial r^2} + \alpha_x (\tau_x - r) \frac{\partial v_2}{\partial r} + \frac{1}{2} p_{\text{def}} (0.1 - p_{\text{def}}) (0.05)^2 \frac{\partial^2 v_2}{\partial p_{\text{def}}^2} + 0.01(0.05 - p_{\text{def}}) \frac{\partial v_2}{\partial p_{\text{def}}} - 0.02 v_1 + (0.10 - p_{\text{def}}) v_1 + (0.9 - 1)v_2 = 0 \quad (5.4a) \]

for all \((t,b,r,p_{\text{def}}) \in (0,T) \times (0, \Gamma_k) \times \partial \Omega_k\), such that

Figure 1. \( v_1(0, b, 0.05, p_{\text{def}}) \).
Figure 2. $v_2(0, b, 0.05, p_{\text{def}})$.

$$v_2\left(t, b, r, p_{\text{def}}\right) = \max\{b - 0.68, 0\},$$

(5.4b)

for $(t, b, r, p_{\text{def}}) \in (0, T) \times (0, \Gamma_4) \times \partial \Omega_4$ and

$$v_2\left(T, b, r, p_{\text{def}}\right) = \max\{b - 0.68, 0\}, \quad (b, r, p_{\text{def}}) \in (0, \Gamma_4) \times \Omega_4$$

(5.4c)

$$v_2\left(t, \Gamma_4, r, p_{\text{def}}\right) = \max\{b - 0.68, 0\}, \quad (t, r, p_{\text{def}}) \in (0, T) \times \Omega_4.$$  

(5.4d)

Figure 1 and Figure 2 show the value function components $v_1(t, b, r, p_{\text{def}})$ and $v_2(t, b, r, p_{\text{def}})$, respectively, for $r = 0.05$. Relative to the discretization of (5.2)-(5.4), we utilized $\delta_t = 0.001$, $\delta_r = 0.001$, $\delta_b = 0.005$, $\delta_p = 0.005$. In particular, we note the effect of the rating based exercise prices on $v_1$ and $v_2$ and the decreasing value of $v_2$ with increasing $p_{\text{def}}$, as expected.

Scientific Research Publishing (SCIRP) is one of the largest Open Access journal publishers. It is currently publishing more than 200 open access, online, peer-reviewed journals covering a wide range of academic disciplines. SCIRP serves the worldwide academic communities and contributes to the progress and application of science with its publication.

Other selected journals from SCIRP are listed as below. Submit your manuscript to us via either submit@scirp.org or Online Submission Portal.
