Abstract

In this paper we give an alternative treatment of the Schrödinger equation with the Morse potential, which based on the exact summation of the Feynman perturbation series in its original form. Using Fourier transform we establish a recurrence equation between terms of the perturbation series. Finally, by the inverse Fourier transform and some technical tools of the ordinary differential equations of the second order, we can compute the exact sum of the perturbation series which is the Green’s function of the problem.

Keywords

Morse Potential; Green’s Function; Propagator; Path Integral; Perturbation Series; Fourier Transform

1. Introduction

In quantum mechanics, the class of potentials for which Schrödinger equation can be exactly solved has been extended considerably by using different methods. The popular and widely one used in quantum mechanics is the perturbation theory leading to solve the problems approximately. Furthermore, among problems that can be exactly solved, there are few whose solutions can be obtained exactly by summing up the perturbation series in the path integral formalism [1]. Exact Green’s functions: for delta-function [2]-[4], for Coulomb potential [5]-[7], for the inverse square potential [8] and for the step potential [9] are obtained by summing up the pertur-
bation series in the path integral framework. In [2], the Feynman perturbation series are used to study the one-di-
mensional delta-function potential, where the authors extracted only correct informations for wave functions but
they did not give the exact expression form of the propagator. The use of the same technique, perturbation series,
gave the exact expression for the propagator for the delta-function potential [3]. We can find several examples
of potentials problem with a delta-function perturbation by means of path integrals [4], the Green’s function for
each problem is derived by summing the Feynman perturbation series. In [5], the perturbation series are used to
derive the Green’s function for the Coulomb potential in a closed analytical form. The Green’s function of the
one-dimensional relativistic Wood-Saxon, step and square well potential are evaluate by the Kleinert’s path
integral technique [6] and in [7] the same author has calculated the Green’s function of the D-dimensional Cou-
lomb by summing exactly the perturbation series; the energy spectra and wave functions are extracted. The exact
propagator is derived by summing the Feynman perturbation series for a particle moving in the inverse square
potential [8]. The Green’s function for the step potential is given by the exact summation of the perturbation se-
ries [9].

The Morse potential is one of the important potentials in physics, which raises many interests in many areas
specialy in molecular physics and is used for the description of the interaction between the atoms in diatomic
molecules. The Schrödinger equation for the Morse potential has been solved exactly or studied by different
methods recently, for example, [10]-[18].

In the paper [19], we have derived the Green’s function of the Morse one-dimensional potential using the
perturbation series, not by summing exactly the series but we use its terms to the final result. The news is that
we have presented the use of the Fourier transform in the Feynman path integral perturbation series method.

In this work, we will use the same technique in [19] and some results of the ordinary differential equations of
the second order. We calculate the Green’s function of the problem by computing the exact sum of the perturba-
tion series, but in a different way as in [19].

2. Path Integral for the Morse Potential via the Sum of the Perturbation Series

We are interested to calculate the propagator, say the Green’s function relative to the one-dimensional Morse
potential:

\[ V(x) = V_0 \left( \exp(-2x) - 2 \exp(-x) \right) \]

which can be written as:

\[ V(x) = 4V_0 \sum_{n=1}^{\infty} \left( -\frac{1}{2} \right)^n \exp(-nx), \]  

where \( V_0 > 0 \) is the strength of the potential. The Feynman propagator is defined, taking \( \hbar = 1 \), by:

\[ K(x,T/x_0,0) = \int_{x(0)=0}^{x(T)=x} D[x(t)] \exp\left( i \int_0^T L(x,\dot{x},t) \, dt \right) \]

where \( L \) is the Lagrangian of the problem and \( D[x(t)] \) is the formal measure on the path space. If we split
the Lagrangian into the free part and the interaction part as (in unit mass):

\[ L(x,\dot{x},t) = \frac{\dot{x}^2}{2} - V(x) \]

We can show that the Feynman propagator takes the form:

\[ K(x,T/x_0,0) = \sum_{n=0}^{\infty} (i)^n K_n(x,T/x_0,0) \]

where:

\[ K_n(x,T/x_0,0) = (-1)^n \int_0^T \cdots \int_0^T \prod_{j=1}^{n} K_0(x_{j-1},t_j/x_j,t_j) \prod_{j=1}^{n} V(x_j) \, dx_j \]

And \( K_0(x_{j-1},t_j/x_j,t_j) \) is the free particle propagator given by:
Taking the Fourier transform of $K_n(x, T/x_0, 0)$ on $T$ as:

$$G_n(x, x_0; E) = G_n(x, x_0) = \frac{1}{i} \int_0^\infty K_n(x, T/x_0, 0) \exp(iET) \, dT$$

we write this last formula as:

$$G_n(x, x_0) = \int_{-\infty}^{\infty} dx_n \, G_0(x, x_n) V(x_n) G_{n-1}(x_n, x_0)$$

where:

$$G_0(x, x_n) = \frac{1}{i} \int_0^\infty K_0(x, T/x_n, 0) \exp(iET) \, dT = \frac{1}{i} \int_0^\infty \frac{1}{\sqrt{2\pi T}} \exp \left(\frac{iET + \frac{i}{2T} (x - x_n)^2}{2}\right) \, dT$$

and using Equations (1) and (9), then (8) becomes:

$$G_n(x, x_0) = -4V_0 \sum_{s=1}^{\infty} \left(-\frac{1}{2}\right)^s \int_0^\infty \frac{1}{\sqrt{2\pi T}} \exp \left(\frac{iET}{2}\right) \, dT \int_{-\infty}^{\infty} dx_n \, \exp \left(-sx_n + \frac{i}{2T} (x - x_n)^2\right) G_{n-1}(x_n, x_0)$$

we take now the Fourier transform on the end point $x$ in the last formula, and using the convolution theorem for Fourier transform, we get:

$$\tilde{G}_n(w, x_0) = -4V_0 \sum_{s=1}^{\infty} \left(-\frac{1}{2}\right)^s \int_0^\infty \frac{1}{\sqrt{2\pi T}} \exp \left(\frac{iET - \frac{\omega^2}{2}}{2}\right) \, dT \, \tilde{G}_{n-1}(\omega + is, x_0)$$

i.e.

$$\tilde{G}_n(w, x_0) = 2iV_0 f_0(\omega) \left[\tilde{G}_{n-1}(\omega + 2i, x_0) - 2\tilde{G}_{n-1}(\omega + i, x_0)\right], \quad n \geq 1;$$

where:

$$\tilde{G}_n(w, x_0) = \int_{-\infty}^{\infty} \exp(i\omega x) G_n(x, x_0) \, dx$$

and

$$f_0(\omega) = i \int_0^\infty dT \exp \left(iT \left(E - \frac{\omega^2}{2}\right)\right) = \frac{2}{2\epsilon^2 + \omega^2}, \quad \text{where} \ E = -\epsilon^2$$

From Equation (12), we see that all terms $\tilde{G}_n(w, x_0)$ are known and depend on the expression of $\tilde{G}_0(\omega + in, x_0)$ which is:

$$\tilde{G}_0(\omega + in, x_0) = \int_{-\infty}^{\infty} \exp \left(i(\omega + in)x\right) G_0(x, x_0) \, dx = -\left(\frac{2}{2\epsilon^2 + (\omega + in)^2}\right) \exp(i\omega - n)x_0$$

where we note $f_n(\omega)$ by:

$$f_n(\omega) = \frac{1}{2\epsilon^2 + (\omega + in)^2}, \quad n = 1, 2, \ldots.$$
Let now compute the first and the second terms of Equation (12):
\[
\tilde{G}_1(w, x_0) = 2iV_0 f_0(\omega) \exp(i\omega x_0) \left[ f_2(\omega) \exp(-2x_0) - 2f_1(\omega) \exp(-x_0) \right]
\]
and
\[
\tilde{G}_2(w, x_0) = 2^2 V_0^2 f_0(\omega) \exp(i\omega x_0) \left[ f_2(\omega) f_4(\omega) \exp(-4x_0) - 2f_1(\omega) f_3(\omega) \exp(-3x_0) - 2f_1(\omega) f_1(\omega) \exp(-3x_0) + 4f_1(\omega) f_3(\omega) \exp(-3x_0) + 4f_1(\omega) f_1(\omega) \exp(-2x_0) \right]
\]
and so on, we can see that all terms \( \tilde{G}_n(w, x_0) \) are determined in a linear combination of \( f_n(\omega) \) and powers of \( \exp(-x_0) \). Since \( \tilde{G}(w, x_0) \) is:
\[
\tilde{G}(w, x_0) = \sum_{n=0}^{\infty} (i)^n \tilde{G}_n(w, x_0)
\]
and if we bring together all terms in power of \( \exp(-x_0) \), we get:
\[
\tilde{G}(w, x_0) = f_0(\omega) \exp(i\omega x_0) \left[ \sum_{n=0}^{\infty} a_n(\omega) \exp(-nx_0) \right]
\]
where the coefficients \( a_n(\omega) \) satisfy the recurrence formula:
\[
a_n(\omega) = 2V_0 f_n(\omega) \left[ 2a_{n-1}(\omega) - a_{n-2}(\omega) \right]
\]
or:
\[
\left[ 2\epsilon^2 + \omega^2 - n^2 + 2i\omega \right] a_n(\omega) = 2V_0 \left[ 2a_{n-1}(\omega) - a_{n-2}(\omega) \right]
\]
with \( a_{-1} = 0, a_0 = -1, a_n(\omega) = -4V_0 f_1(\omega), \cdots, \text{etc.} \).

Now noting the series in Equation (17) by:
\[
\tilde{f}(w, x_0) = f_0(\omega) \sum_{n=0}^{\infty} a_n(\omega) X^n = \tilde{G}(w, x_0) \exp(-i\omega x_0)
\]
we can easily check that \( F(X) \) which is the generating function of \( a_n(\omega) \) satisfies the differential equation:
\[
X^2 \frac{d^2}{dx^2} F(X) + X \left( 1 - 2i\omega \right) \frac{d}{dx} F(X) - \left( 2\epsilon^2 + \omega^2 - 4XV_0 + 2X^2 V_0 \right) F(X) = 2\epsilon^2 + \omega^2
\]
Here we have to note that this equation is equivalent to those governing Green’s function itself but written in an other form where we have put \( X = \exp(-x_0) \) and done the Fourier transform on the end point \( x \), i.e.:
\[
\left[ -\frac{1}{2} \frac{d^2}{dx_0^2} + V(x_0) + \epsilon^2 \right] G(x, x_0/E) = -\delta(x_0 - x)
\]
Return now to Equation (17) and if we take the inverse Fourier Transorm on \( \tilde{G}(w, x_0) \), we obtain:
\[
G(x, x_0) = \frac{1}{2\pi} \sum_{n=0}^{\infty} \int d\omega \exp(-i\omega(x-x_0)) f_0(\omega) a_n(\omega) \exp(-nx_0)
\]
Then if we note by:
\[
A_n(x-x_0) = \frac{1}{2\pi} \int d\omega \exp(-i\omega(x-x_0)) f_0(\omega) a_n(\omega)
\]
we see that:
\[
G(x, x_0) = \sum_{n=0}^{\infty} A_n(x-x_0) \exp(-nx_0)
\]
and with the Fourier transform properties, we have:
\[ \omega^2 f_0(\omega) a_0(\omega) = -\int_{-\infty}^{\infty} \omega \exp(i \omega x) \frac{d^2}{dx^2} A_\omega(x) \]  
\[ i \omega f_0(\omega) a_0(\omega) = -\int_{-\infty}^{\infty} \omega \exp(i \omega x) \frac{d}{dx} A_\omega(x) \] (26) (27)

Then from these last formulas and the recurrence formula of \( a_\omega(\omega) \) (19) we conclude that \( A_\omega(x) \) satisfies:

\[ \frac{d^2}{dx^2} A_\omega(x) - 2n \frac{d}{dx} A_\omega(x) + \left( 2\epsilon^2 - n^2 \right) A_\omega(x) = 4V_0 A_{n-1}(x) - 2V_0 A_{n-2}(x) \]  
\[ -\int_{-\infty}^{\infty} \omega \exp(i \omega x) \frac{d}{dx} A_\omega(x) \] (28)

with \( A_{n,0}(x) = 0 \) and \( A_\omega(x) = -\exp(-\sqrt{2}\epsilon |x|) \), which is a linear second order ordinary differential equation with real constant coefficients. Then \( A_\omega(x) \) can be expressed in term of the complementary solution plus a particular solution. Indeed, the complementary solution \( A_\omega(x) \) is:

\[ A_\omega(x) = C_1^\omega \exp\left(-\left(n + \epsilon\sqrt{2}\right)x\right) + C_2^\omega \exp\left(-\left(n - \epsilon\sqrt{2}\right)x\right) \] (29)

where the coefficients \( C_1^\omega \) and \( C_2^\omega \) are constants independent of \( x \) and using the variation of parameters method we find that the particular solution has the following expression:

\[ A_p^\omega(x) = C_1^\omega \exp\left(-\left(n + \epsilon\sqrt{2}\right)x\right) + C_2^\omega \exp\left(-\left(n - \epsilon\sqrt{2}\right)x\right) \] (30)

with \( C_1^\omega(x), C_2^\omega(x) \) are determined by:

\[ \frac{d}{dx} C_1^\omega = \frac{V_0}{\epsilon\sqrt{2}} \exp\left(\epsilon\sqrt{2}\epsilon x\right) \left[ 2 \exp(x) B_{n-1}(x) - \exp(2x) B_{n-2}(x) \right] \] (31)

\[ \frac{d}{dx} C_2^\omega = -\frac{V_0}{\epsilon\sqrt{2}} \exp\left(-\epsilon\sqrt{2}\epsilon x\right) \left[ 2 \exp(x) B_{n-1}(x) - \exp(2x) B_{n-2}(x) \right] \] (32)

where

\[ B_n(x) = A_n(x) \exp(nx), \quad B_{n,0}(x) = 0 \quad \text{and} \quad B_0(x) = -\exp(-\sqrt{2}\epsilon |x|). \]

Finally by recurrence, we can prove that:

\[ A_n^\omega(x) = \begin{cases} 
\left(-1\right)^{n+1} V_0 \overline{b}_n(\epsilon) \exp(-\epsilon\sqrt{2}\epsilon x), & x > 0 \\
\left(-1\right)^{n+1} V_0 \overline{b}_n(-\epsilon) \exp(\epsilon\sqrt{2}\epsilon x), & x < 0
\end{cases} \] (33)

where the coefficients \( b_n(\epsilon) \) satisfy an recurrence formula as:

\[ \left[n^2 \pm 2n\epsilon\sqrt{2}\right] b_n(\mp\epsilon) = 4b_{n+1}(\mp\epsilon) + 2b_{n-2}(\mp\epsilon) \] (34)

with \( b_0(\mp\epsilon) = 0, \quad b_0(\pm\epsilon) = 1 \).

Then from Equations (29) and (33) we have:

\[ A_\omega(x) = A_\omega^\prime(x) + A_\omega(x) = C_1^\omega \exp\left(-\left(n + \epsilon\sqrt{2}\right)x\right) + C_2^\omega \exp\left(-\left(n - \epsilon\sqrt{2}\right)x\right) 
\begin{cases} 
\left(-1\right)^{n+1} V_0 \overline{b}_n(\epsilon) \exp(-\epsilon\sqrt{2}\epsilon x), & x > 0 \\
\left(-1\right)^{n+1} V_0 \overline{b}_n(-\epsilon) \exp(\epsilon\sqrt{2}\epsilon x), & x < 0
\end{cases}, \quad \forall n \geq 0. \] (35)
we have to note that \( C_0^1 = C_0^2 = 0 \).

Knowing that if the following limits exist:
\[
\lim_{x \to -\infty} \sum_{n=0}^{\infty} C_n^1 \exp(-nx) \neq 0 \quad \text{and} \quad \lim_{x \to +\infty} \sum_{n=0}^{\infty} C_n^2 \exp(-nx) \neq 0
\]
then
\[
\lim_{x \to -\infty} \left[ \exp(\varepsilon \sqrt{2} x) \sum_{n=0}^{\infty} C_n^1 \exp(-nx) \right] = +\infty
\]
\[
\lim_{x \to +\infty} \left[ \exp(-\varepsilon \sqrt{2} x) \sum_{n=0}^{\infty} C_n^2 \exp(-nx) \right] = +\infty
\]

So in that case and from the formulas (35), (25), we are able to write the Green’s function \( G(x, x_0) \) as:
\[
G(x, x_0) = \begin{cases} \exp(-\varepsilon \sqrt{2} (x - x_0)) \sum_{n=0}^{\infty} \left( \frac{-(1)^{n+1}}{\varepsilon \sqrt{2}} b_n(\varepsilon) \exp(-nx_0) + C_n^1(x_0) \exp(-nx) \right), & x > x_0 \\ \exp(\varepsilon \sqrt{2} (x - x_0)) \sum_{n=0}^{\infty} \left( \frac{-(1)^{n+1}}{\varepsilon \sqrt{2}} b_n(-\varepsilon) \exp(-nx_0) + C_n^2(x_0) \exp(-nx) \right), & x_0 > x \end{cases}
\]

Knowing that the generating functions of \( b_n(\varepsilon) \) and \( b_n(-\varepsilon) \) respectively are:
\[
F_i(X) = \sum_{n=0}^{\infty} b_n(\varepsilon)(-X)^n, \quad F_i(X) = \sum_{n=0}^{\infty} b_n(-\varepsilon)(-X)^n;
\]
then if we use the recurrence formula (34) it’s easy to deduce that these generating functions are given by:
\[
F_i(X) = X^{i-\frac{1}{2}}G \left[ \frac{2}{2V_0}X \right], \quad F_i(X) = X^{-i-\frac{1}{2}}G \left[ \frac{2}{2V_0}X \right];
\]
where \( G(y) \) is the solution of Whittaker equation:
\[
G^*(y) + \frac{1}{4} \left[ \frac{\sqrt{2V_0}}{y} + \frac{1}{4} - \frac{2\varepsilon}{y^2} \right] G(y) = 0
\]
and they satisfy respectively the following differential equations:
\[
X^2 F'_i(X) + X \left( 1 - 2\varepsilon \sqrt{2} \right) F'_i(X) + 2X \left( 2 - \frac{X}{V_0} \right) F_i(X) = 0
\]
\[
X^2 F'_i(X) + X \left( 1 + 2\varepsilon \sqrt{2} \right) F'_i(X) + 2X \left( 2 - \frac{X}{V_0} \right) F_i(X) = 0
\]

hence we can conclude that the Green’s function \( G(x, x_0) \) takes the form:
\[
G(x, x_0) = \begin{cases} C_1(x) \exp \left( \frac{x_0}{2} \right) W_{\frac{\varepsilon}{\sqrt{2}V_0}} \left[ 2\sqrt{2V_0} \exp(-x_0) \right] + \exp(-\varepsilon \sqrt{2} (x - x_0)) \sum_{n=0}^{\infty} C_n^1(x_0) \exp(-nx), & x > x_0 \\ C_2(x) \exp \left( \frac{x_0}{2} \right) M_{\frac{\varepsilon}{\sqrt{2}V_0}} \left[ 2\sqrt{2V_0} \exp(-x_0) \right] + \exp(\varepsilon \sqrt{2} (x - x_0)) \sum_{n=0}^{\infty} C_n^2(x_0) \exp(-nx), & x_0 > x \end{cases}
\]
where \( W_{\frac{\varepsilon}{\sqrt{2}V_0}} \), \( M_{\frac{\varepsilon}{\sqrt{2}V_0}} \) are the Whittaker’s functions. We draw attention here that in this last formula we have taken the Whittaker’s function \( W_{\frac{\varepsilon}{\sqrt{2}V_0}} \) in the case \( x > x_0 \) because it’s not singular at \( +\infty \) (i.e. \( x_0 \to -\infty \)), and when \( x_0 > x \) we have taken \( M_{\frac{\varepsilon}{\sqrt{2}V_0}} \) which is not singular at \( 0 \) (i.e. \( x_0 \to +\infty \)). Let us now to go back
to (8) \emph{i.e.}:

\begin{align*}
G_n(x, x_0) &= i \int_{-\infty}^{\infty} dx_n G_0(x, x_n) V(x_n) G_{n-1}(x_n, x_0)
\end{align*}

for which it’s obvious that:

\begin{align*}
G_n(x, x_0) &= i \int_{-\infty}^{\infty} dx_i G_{n-1}(x, x_i) V(x_i) G_0(x_i, x_0)
\end{align*}

(43)

from this formula and with the same way as above, if we take the Fourier transform on initial point \( x_0 \) we can see that \( G(x, x_0) \) have another form as:

\begin{align*}
G(x, x_0) &= \begin{cases} 
C_1(x_0) \exp \left( \frac{x}{2} \right) W_{\mathcal{F}_{V_0}, \mathcal{F}} \left[ 2 \sqrt{2V_0} \exp (-x) \right] + \exp \left( -\varepsilon \sqrt{2} (x_0 - x) \right) \sum_{n=0}^{\infty} C_n(x) \exp (-nx_0), & x_0 < x \\
C_2(x_0) \exp \left( \frac{x}{2} \right) M_{\mathcal{F}_{V_0}, \mathcal{F}} \left[ 2 \sqrt{2V_0} \exp (-x) \right] + \exp \left( \varepsilon \sqrt{2} (x_0 - x) \right) \sum_{n=0}^{\infty} C_n^2(x) \exp (-nx_0), & x > x_0
\end{cases}
\end{align*}

(44)

then from Equation (42) and this last formula (44) we have for \( x > x_0 \):

\begin{align*}
C_1(x) \exp \left( \frac{x_0}{2} \right) W_{\mathcal{F}_{V_0}, \mathcal{F}} \left[ 2 \sqrt{2V_0} \exp (-x) \right] &= \exp \left( -\varepsilon \sqrt{2} (x_0 - x) \right) \sum_{n=0}^{\infty} C_n(x) \exp (-nx_0)
\end{align*}

(45)

and

\begin{align*}
C_2(x_0) \exp \left( \frac{x}{2} \right) M_{\mathcal{F}_{V_0}, \mathcal{F}} \left[ 2 \sqrt{2V_0} \exp (-x) \right] &= \exp \left( \varepsilon \sqrt{2} (x_0 - x) \right) \sum_{n=0}^{\infty} C_n^2(x) \exp (-nx)
\end{align*}

(46)

for which Equation (44) \emph{i.e.} \( G(x, x_0) \) becomes:

\begin{align*}
G(x, x_0) &= \begin{cases} 
C_1(x) \exp \left( \frac{x_0}{2} \right) W_{\mathcal{F}_{V_0}, \mathcal{F}} \left[ 2 \sqrt{2V_0} \exp (-x) \right] + C_2(x_0) \exp \left( \frac{x}{2} \right) M_{\mathcal{F}_{V_0}, \mathcal{F}} \left[ 2 \sqrt{2V_0} \exp (-x) \right], & x > x_0 \\
C_1(x_0) \exp \left( \frac{x}{2} \right) W_{\mathcal{F}_{V_0}, \mathcal{F}} \left[ 2 \sqrt{2V_0} \exp (-x) \right] + C_2(x) \exp \left( \frac{x_0}{2} \right) M_{\mathcal{F}_{V_0}, \mathcal{F}} \left[ 2 \sqrt{2V_0} \exp (-x) \right], & x_0 > x
\end{cases}
\end{align*}

(47)

Knowing that \( F_1(X) \) is a solution of the differential Equation (40), then it’s easy to check that \( X^{\varepsilon} \mathcal{F}_{V_0} F_1(X) \) is a solution of the following differential equation:

\begin{align*}
X^2 \frac{d^2}{dx^2} H(X) + X \frac{d}{dx} H(X) - \left( 2 \varepsilon^2 - 2X \left( 2 - \frac{X}{V_0} \right) \right) H(X) = 0
\end{align*}

(48)

which is the same as the following differential equation:

\begin{align*}
\left[ -\frac{d^2}{dx^2} + V(x) + \varepsilon^2 \right] H(x) = 0
\end{align*}

(49)

for \( X = V_0 \exp(-x) \). Then we conclude that:

\begin{align*}
H_1(x) &= \exp \left( \frac{x}{2} \right) W_{\mathcal{F}_{V_0}, \mathcal{F}} \left[ 2 \sqrt{2V_0} \exp (-x) \right]
\end{align*}

and

\begin{align*}
H_2(x) &= \exp \left( \frac{x}{2} \right) M_{\mathcal{F}_{V_0}, \mathcal{F}} \left[ 2 \sqrt{2V_0} \exp (-x) \right]
\end{align*}

which are two linearly independent solutions of Equation (49), and since \( G(x, x_0) \) is also solution of the differential Equation (13) for \( x > x_0 \), form Equation (47) we can deduce that:
Finally we get that the Green’s function for Morse potential takes the form:

\[
G(x, x_0) = \begin{cases} 
\frac{1}{2} \left(1 + \frac{\sqrt{2}E - \sqrt{2V_0}}{\Gamma} \right) \exp \left( \frac{x + x_0}{2} \right) \\
\Theta(x - x_0) \exp \left( \frac{x + x_0}{2} \right) M_{\sqrt{V_0}, \sqrt{V_0}} \left[ 2\sqrt{2V_0} \exp(-x) \right] W_{\sqrt{V_0}, \sqrt{V_0}} \left[ 2\sqrt{2V_0} \exp(-x_0) \right] \\
+ \Theta(x_0 - x) \exp \left( \frac{x + x_0}{2} \right) M_{\sqrt{V_0}, \sqrt{V_0}} \left[ 2\sqrt{2V_0} \exp(-x_0) \right] W_{\sqrt{V_0}, \sqrt{V_0}} \left[ 2\sqrt{2V_0} \exp(-x) \right] 
\end{cases} 
\]

where \( \Theta \) denotes Heaviside’s unit step function. A result was found earlier by different methods [11]-[13].

3. Conclusion
In this work, we have calculated the Green’s function for the Morse potential using the perturbation method in the path integral formalism. This contribution concerns, for the first time, the calculation of the energy Green’s function of the system by summing exactly the perturbation series with the introduction of the Fourier transform and some results concerning the Green’s function of the ordinary differential equations of the second order. We will consider a generalization of this method specialy for other special potentials in the exponential form.
