ABSTRACT

Partition-and-Recur (PAR) method is a simple and useful formal method. It can be used to design and testify algorithmic programs. In this paper, we propose that PAR method is an effective formal method on solving combinatorics problems. Furthermore, we formally derive combinatorics problems by PAR method, which cannot only simplify the process of algorithmic program’s designing, but also improve its automatization, standardization and correctness. We develop algorithms for two typical combinatorics problems, the number of string scheme and the number of error permutation scheme. Lastly, we obtain accurate C++ programs which are transformed by automatic transforming system of PAR platform.

Keywords: PAR Method, Formal Derivation, Combinatorics, Algorithmic Programs

1. Introduction

Computer Science is a science of developing correct and efficient algorithms. Its main research object is discrete data handled by computer. As long as the algorithm involves iterant calculation, each traditional strategy of algorithm design can embody the principle of partition and recurrence. Partition is a general approach for dealing with complicated objects and is typically used in divide-and-conquer approach. Recurrence is used in algorithm analysis and dynamic programming approach. PAR method is a unified approach of developing efficient algorithmic programs and its key idea is partition and recurrence. Using PAR method, we begin from the formal specification of a specified problem, partition the problem into a couple of sub problems, and develop an efficient and correct algorithm represented by recurrence and initiation [1–3].

Combinatorics is a science of studying discrete objects. In general, it includes basic theories, counting methods and algorithms widely used in combination. Combinatorics algorithms are based on combinatorics and make people feel that computer may have its own thought.

However, many programming teaching materials can only present combinatorics algorithms but cannot provide the formal derived procedures that design the specific algorithms from the unresolved combinatorics problems. So algorithm designers cannot understand the essence of algorithms and cannot improve their capability of algorithm design [4].

PAR method embodies rich mathematical ideology, it provides many powerful tools and appropriate developing environment. We can avoid making a choice among various design methods by adopting PAR method to develop combinatory algorithms. It can also change many creative labor to mechanized labor, and can finally improve algorithmic programs design’s automatization, standardization and correctness [5,6].

In this paper, we propose that PAR method is an effective formal method on solving combinatorics problems. We formally derive several typical algorithms of combinatorics problems by PAR method, which cannot only solve the above problems, but also can assure their correctness on logic. These combinatorics problem instances include the number of string scheme, the number of error permutation scheme, maximum summary [4], the longest common subsequence [4], minimum spanning tree [4,7] and the Knapsack problem [4], etc. Because of the limited space, we only describe the whole developing process of two specific combinatorics problem instances, the number of string scheme and the number of error permutation scheme, which are derived by PAR methods.

2. The Developing Steps of the Number of String Scheme Derived by PAR Methods

Suppose that \( A = \{a, b, c, d\} \), \( n \) is given, and we want to
select \( n \) elements to compose string, in which element \( a \) and \( b \) cannot be adjacent elements. How many schemes are there in a string with \( n \) elements? [4]

2.1 The Formal Function Specification of the Number of String Scheme

**PQ:** Given integer \( n \), set \( A = \{a, b, c, d\} \), string \( S \) stores \( n \) elements of set \( A \).

**PR:** Let \( \text{String}(n) = \{S[S][k] = a \lor S[k] = b \lor S[k] = c \lor S[k] = d \land 1 \leq k < n\} \) and \( F(S, i) = \forall(j : i \leq j < n : S[j..j+1] \neq ab \land S[j..j+1] \neq ba) \), then

\[
Z_n = N(S : S \in \text{String}(n) : \\
\forall(j : 1 \leq j < n : S[j..j+1] \neq ab \land S[j..j+1] \neq ba)) = \{\text{According to the definition of } F(S, i)\} \\
= \{\text{equivalent transformation of quantifier}\} \\
\sum(S : S \in \text{String}(n) \land F(S, 1) : 1) \quad (1)
\]

2.2 Partition the Problem Based on the Post-Assertion

We partition computing \( X_n \) into computing \( X_n \) and \( Y_n \), each of that has the same structure with \( Z_n \).

\[
X_n = \sum(S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = a \lor S[1] = b) : 1) \quad (2)
\]

In Equation (2), \( X_n \) denote the number of \( n \) elements’ string scheme that element \( a \) and \( b \) cannot be adjacent elements and the initial element is \( a \) or \( b \).

\[
Y_n = \sum(S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = c \lor S[1] = d) : 1) \quad (3)
\]

In Equation (3), \( Y_n \) denote the number of \( n \) elements’ string scheme that element \( a \) and \( b \) cannot be adjacent elements and the initial element is \( c \) or \( d \).

\[
Z_n = \sum(S : S \in \text{String}(n) \land F(S, 1) : 1) = \sum(S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = a \lor S[1] = b \lor S[1] = c \lor S[1] = d) : 1) \land \{\text{Range Disjunction}\} \\
\sum(S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = a \land S[1] = b) : 1) + \\
\sum(S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = c \land S[1] = d) : 1) = \{\text{According to the definition of } X_n \text{ and } Y_n\} \\
X_n + Y_n \quad (4)
\]

According to the equation (4), we can partition computing \( Z_n \) into computing \( X_n \) and \( Y_n \).

2.3 Construct the Recurrence Relation

Suppose \( X_{n-1} \) denotes the number of \( n \) elements’ string scheme that satisfy the condition and the initial element is \( a \) or \( b \). \( Y_{n-1} \) denotes the number of \( n \) elements’ string scheme that satisfy the condition and the initial element is \( c \) or \( d \).

\[
X_n = \sum(S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = a \lor S[1] = b) : 1) \\
= \sum(S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = a) : 1) + \\
\sum(S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = b) : 1)
\]

\[
Y_n = \sum(S : S \in \text{String}(n) \land F(S, 1) : 1) = \sum(S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = c \lor S[1] = d) : 1) \\
= \sum(S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = c) : 1) + \\
\sum(S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = d) : 1)
\]

According to the equation (5), we can partition computing \( X_n \) into computing \( X_{n-1} \) and \( 2 \times Y_{n-1} \).

\[
X_n = X_{n-1} + 2 \times Y_{n-1} \quad (5)
\]
Formal Derivation of the Combinatorics Problems with PAR Method

\[ \sum (S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = c \lor S[2] = d)) \]
\[ \land (S[2] = a \lor S[2] = b) : 1) + \]
\[ \sum (S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = d)) \]
\[ \land (S[2] = a \lor S[2] = b) : 1) + \]
\[ \sum (S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = c)) \]
\[ \land (S[2] = c \lor S[2] = d) : 1) + \]
\[ \sum (S : S \in \text{String}(n) \land F(S, 1) \land (S[1] = d)) \]
\[ \land (S[2] = c \lor S[2] = d) : 1) \]
\[ = \{\text{Range Disjunction}\} \]
\[ = \{\text{According to the definition of } F(S, i)\} \]
\[ \sum (S : S \in \text{String}(n) \land (S[1] = c) \land F(S, 2)) \]
\[ \land (S[2] = a \lor S[2] = b) : 1) + \]
\[ \sum (S : S \in \text{String}(n) \land (S[1] = d) \land F(S, 2)) \]
\[ \land (S[2] = a \lor S[2] = b) : 1) + \]
\[ \sum (S : S \in \text{String}(n) \land (S[1] = c) \land F(S, 2)) \]
\[ \land (S[2] = c \lor S[2] = d) : 1) + \]
\[ \sum (S : S \in \text{String}(n) \land (S[1] = d) \land F(S, 2)) \]
\[ \land (S[2] = c \lor S[2] = d) : 1) \]
\[ = \{\text{According to the definition of } X_{i-1} \text{ and } Y_{n-1}\} \]
\[ 2 \times X_{n-1} + 2 \times Y_{n-1} \quad (6) \]

According to the equation (6), we can also partition computing \( Y_{n} \) into computing \( 2 \times X_{n-1} \) and \( 2 \times Y_{n-1} \).

2.4 Developing Loop Invariant

Suppose variant \( x \) stores the value of \( X_{n} \), variant \( u \) stores the value of \( X_{i-1} \), variant \( y \) stores the value of \( Y_{n} \), variant \( v \) stores the value of \( Y_{i-1} \), variant \( z \) stores the value of \( Z_{n} \), where \( X_{1} = 2, Y_{1} = 2, Z_{n} = 4 \).

LI: \[ x = X_{i} \land u = X_{i-1} \land y = Y_{i} \land v = Y_{i-1} \land z = Z_{i} \]
\[ \land (1 \leq i \leq n) \]

2.5 Developing Corresponding \( \text{RADL} \) Program

The Recurrence-based Algorithm Design Language (\( \text{RADL} \)) program of the number of string scheme, derived by \( \text{PAR} \) methods, is shown in Algorithm 1. By the automatic program transforming system of \( \text{PAR} \) platform, we can get the Abstract Programming Language (\( \text{APLA} \)) program of the number of string scheme which is transformed from the \( \text{RADL} \) program and is shown in Algorithm 2. Finally, we transform the \( \text{APLA} \) program of the number of string scheme to \( \text{C++} \) program, which can get accurate running result.

Algorithm 1 (\( \text{The RADL program of string scheme} \))

\[[\text{in} n:\text{integer}; \ i:\text{integer}; \ x,y,u,v:\text{integer}; \ \text{out} \ z:\text{integer};]\]
\[ \text{Begin: } i=1; \ x=2; \ y=2; \ z=4; \]
\[ A_1: \ x = x(i) \land u = x(i+1) \land y = y(i) \land \]
\[ v = v(i+1) \land z = z(i) \land (1 \leq i \leq n) \]
\[ \text{Termination: } i=n; \]
\[ \text{Recur: } u=x+2*y; \ v=2*x+2*y; \]
\[ z=u+v; \ x=u; \ y=v; \]
\[ \text{End.} \]

Algorithm 2 (\( \text{The APLA program of string scheme} \))

\[ \text{var: } n:\text{integer}; \ i:\text{integer}; \ x,y,u,v:\text{integer}; \ z:\text{integer};\]
\[ \text{begin: } \]
\[ \text{write(“Please input integer n value”); } \]
\[ \text{read(n);} \]
\[ i:=1; \ x:=2; \ y:=2; \ z:=4; \]
\[ \text{do (¬(i=n)) → } \]
\[ u:=x+2*y; \]
\[ v:=2*x+2*y; \]
\[ z:=u+v; \]
\[ x:=u; \]
\[ y:=v; \]
\[ i:=i+1; \]
\[ \text{od } \]
\[ \text{write(“The Number of string scheme”: z);} \]
\[ \text{end.} \]

3. The Developing Steps of the Number of Error Permutation Scheme Derived by \( \text{PAR} \) Methods

Suppose that the original arrange scheme is \( A = [a_1 \ldots a_i \ldots a_n] \), which is satisfied with each element is different. We want to interlace \( n \) elements of original permutation scheme \( A \) to compose new permutation scheme \( B \), in which each element cannot be the same position in \( A \). How many schemes are there in error permutation with \( n \) elements? [4]

3.1 The Formal Function Specification of the Number of Error Permutation Scheme

PQ: Given the original permutation scheme \( A = [a_1 \ldots a_i \ldots a_n] \), which is satisfied with \( \forall(i,j): \)
(1 ≤ i < j ≤ n) : (A[i] ≠ A[j])

**PR:** Let \( \text{Perm}(A) = \{ B \mid B[j] = A[i] \land B[j] ≠ B[k]\) \(\land 1 ≤ i, j, k ≤ n \land j ≠ k \} \), then

\[ D_n = N \{ B : B \in \text{Perm}(A) \land \forall \{ j : 1 ≤ j ≤ n : B[j] ≠ A[j] \}\) \]

= \{ equivalent transformation of quantifier \}

\[ \sum (B : B \in \text{Perm}(A) \land \forall \{ j : 1 ≤ j ≤ n : B[j] ≠ A[j] \}) : 1 \]

\(= \exists (i : 1 ≤ i < n : B[n] = A[i] \land B[i] = A[n] : 1) \) \hspace{1cm} (7)

3.2 Partition the Problem Based on the Post-Assertion

We partition computing \( D_n \) into computing \( U_n \) and \( V_n \), each of that has the same structure with \( D_n \).

\[ U_n = \sum (B : B \in \text{Perm}(A) \land \forall \{ j : 1 ≤ j ≤ n : B[j] ≠ A[j] \}) \]

\(\land \exists' (i : 1 ≤ i < n : B[n] = A[i] \land B[i] = A[n] : 1) \) \hspace{1cm} (8)

In Equation (8), \( U_n \) denotes the number of \( n \) elements’ error permutation scheme in which \( a_n \) must be the \( i^{th} \) element in new permutation \( B \).

\[ V_n = \sum (B : B \in \text{Perm}(A) \land \forall \{ j : 1 ≤ j ≤ n : B[j] ≠ A[j] \}) \]

\(\land \exists' (i : 1 ≤ i < n : B[n] = A[i] \land B[i] ≠ A[n] : 1) \) \hspace{1cm} (9)

In Equation (9), \( V_n \) denotes the number of \( n \) elements’ error permutation scheme in which \( a_n \) cannot be the \( i^{th} \) element in new permutation \( B \).

\[ D_n = \sum (B : B \in \text{Perm}(A) \land \forall \{ j : 1 ≤ j ≤ n : B[j] ≠ A[j] \}) \]

= \{ Range Disjunction \}

\[ \sum (B : B \in \text{Perm}(A) \land \forall \{ j : 1 ≤ j ≤ n : B[j] ≠ A[j] \}) \]

\[ \sum (B : B \in \text{Perm}(A) \land \forall \{ j : 1 ≤ j ≤ n : B[j] ≠ A[j] \}) \]

= \{ According to the definition of \( U_n \) and \( V_n \} \)

\[ U_n + V_n \] \hspace{1cm} (10)

According to the equation (10), we can partition computing \( D_n \) into computing \( U_n \) and \( V_n \).

3.3 Construct the Recurrence Relation

Suppose \( D_{n,1} \) denotes the number of \( n \)-1 elements’ error permutation scheme, \( D_{n,2} \) denotes the number of \( n \)-2 elements’ error permutation scheme.

\[ U_n = \sum (B : B \in \text{Perm}(A) \land \forall \{ j : 1 ≤ j ≤ n : B[j] ≠ A[j] \}) \]

= \{ Generalized Range Disjunction \}

\[ \sum (i : 1 ≤ i < n : \sum (B : B \in \text{Perm}(A) \land \forall \{ j : 1 ≤ j ≤ n : B[j] ≠ A[j] \}) \]

\(\land \forall (j : 1 ≤ i < j i < j ≤ n : B[j] ≠ A[j] : 1) \)

= \{ According to the initial definition of \( D_n \}

\[ \sum (i : 1 ≤ i < n : D_{n-2}) \]

\(= (n-1) \times D_{n-2} \) \hspace{1cm} (11)

According to the equation (11), we can partition computing \( U_n \) into computing \((n-1) \times D_{n-2} \).

\[ V_n = \sum (B : B \in \text{Perm}(A) \land \forall \{ j : 1 ≤ j ≤ n : B[j] ≠ A[j] \}) \]

= \{ Generalized Range Disjunction \}

\[ \sum (i : 1 ≤ i < n : \sum (B : B \in \text{Perm}(A) \land \forall \{ j : 1 ≤ j ≤ n : B[j] ≠ A[j] \}) \]

\(\land \forall (j : 1 ≤ i < j i < j ≤ n : B[j] ≠ A[j] : 1) \)

= \{ According to the initial definition of \( D_n \}

\[ \sum (i : 1 ≤ i < n : D_{n-1}) \]

\(= (n-1) \times D_{n-1} \) \hspace{1cm} (12)

According to the equation (12), we can partition computing \( V_n \) into computing \((n-1) \times D_{n-1} \).

According to the equation (10), (11), (12), we have the recurrence: \( D_n = U_n + V_n = (n-1) \times (D_{n,1} + D_{n,2}) \), where \( D_{1,1} = 0, D_{1,2} = 1 \). That is to say, we can partition computing \( D_n \) into computing \((n-1) \times D_{n,1} \) and \((n-1) \times D_{n,2} \).

3.4 Developing Loop Invariant

Suppose variant \( s1 \) stores the value of \( d(i-2) \), variant \( s2 \)
Formal Derivation of the Combinatorics Problems with PAR Method

stores the value of \(d(i-1)\), variant \(d\) stores the value of \(d(i)\), where \(D_1=0, D_2=1\).

1. LI: \(s1 = d(i-2) \land s2 = d(i-1) \land d = d(i) \land (1 \leq i \leq n)\)

3.5 Developing Corresponding RADL Program

The RADL program of the number of error permutation scheme, derived by the PAR methods, is shown in Algorithm 3. By the automatic program transforming system of PAR platform, we can get the APLA program of the number of error permutation scheme which is transformed from the RADL program and is shown in Algorithm 4. Finally, we transform the APLA program of the number of error permutation scheme to C++ program, which can get accurate running result.

Algorithm 3 (The RADL program of error permutation scheme)

```
[\text{in n:integer; i,s1,s2: integer; out d:integer;}] \{\text{PQ} \land \text{PR}\}
\text{Begin: } i=3++1; s1=0; s2=1;
\text{A_I: } s1 = d(i-2) \land s2 = d(i-1) \land d = d(i)
\land (3 \leq i \leq n)
\text{Termination: } i=n+1;
\text{Recur: } d = (i-1)*(s1+s2); s1=s2; s2=d;
\text{End.}
```

Algorithm 4 (The APLA program of error permutation scheme)

```
\text{var: n:integer; i:integer; s1,s2: integer; d:integer; begin:}
\text{write("Please input integer n value");}
\text{read(n);}
\text{i:=2;s1:=0;s2:=1;}
\text{do (¬(i=n)) →}
\quad d = (i-1)*(s1+s2); s1:=s2; s2:=d; i:=i+1;
\text{end}
\text{write("The Interlaced Arrange Scheme: ", z);} \end{verbatim}

4. Conclusions

We developed algorithmic programs for the number of string scheme and the number of error permutation scheme which are typical combinatorics problems. It is revealed that PAR method has particular merit. It is apt to understand and demonstrate the ingenuity and correctness of an algorithm by formula deduction. Compared with other derivation, our algorithmic programs are more precise and simple than the representation of algorithm in natural language, flowchart and program. It also shows that using PAR method in developing combinatorics problem is a very natural meaningful research work. This can not only expand the application of PAR method, but also prove that the PAR method is a unified and effective approach on solving combinatorics problems.
