Abstract

Pure and Antimony (Sb, x = 0.01%, 0.02% and 0.03%) doped Bi$_{0.5}$Na$_{0.5}$TiO$_3$ electro ceramics were successfully synthesized by a conventional solid state reaction route. X-ray diffraction analysis showed that a distinct 002/200 peak splitting appears when doping percentage changes from 0.02 to 0.03, referring to a hexagonal symmetry. The data show the Lorentzian deconvolution of the 002 and 200 peaks of the tetragonal phase and the 202 peak of the rhombohedral phase. There is no significant change in the Raman spectra for the prepared compositions while some additional peaks around 151, 281, 585 and 853 cm$^{-1}$ compared to the peaks observed in BNT. It may be possible that a morphotrophic phase boundary (MPB) exists around $x = 0.03$. Analysis of peak positions, widths and intensities of Raman spectroscopy study also confirmed the existence of structural change around $x = 0.03$ composition.

Keywords

Ceramics, X-Ray Diffraction, Raman Spectroscopy

1. Introduction

The ferroelectric perovskite-type ceramic materials having general formula ABO$_3$ with different cationic distributions at A/B-sites are being investigated due to their important device applications such as in capacitors, piezoelectric ultrasonic transducers, electrostrictive actuators, SAW substrates, etc. [1]-[3]. The doping or composi-
tional changes in these ceramics can control the high electromechanical characteristics. Bismuth sodium titanate, Bi$_{0.5}$Na$_{0.5}$TiO$_3$ (BNT) [4] is one of the important ferroelectrics among the lead-free piezoelectric materials with large remnant polarization ($P_r = 38 \ \mu$C/cm$^2$), high Curie temperature ($T_c = 320^\circ$C), and shows diffuse phase transition (DPT) with perovskite structure. In addition to the DPT, two more phase transitions were reported at 230$^\circ$C and at 500$^\circ$C - 600$^\circ$C. It is observed that the coexistence of the cubic and the tetragonal phases in the temperature ranges from 500$^\circ$C to 540$^\circ$C, and the tetragonal and the rhombohedral phases from 255$^\circ$C to 400$^\circ$C [5]. Several of its crystal structures, including cubic, tetragonal and rhombohedral, have been studied [6] [7] over different temperature ranges.

Relaxor behaviour of BNT depends on substitution in both A-site and B-site [8] and also it has been observed that the dopants control the phase transitions, electromechanical properties, relaxor behaviour and the piezoelectric coefficients. Many studies have been performed on BNT to understand the effect of dopants on structural and electrical properties of the material. Some studies focus on dielectric properties, while others focus on piezoelectric properties. BNT is a good material for both applications because it can be modified to enhance a specific desirable behaviour. Both A-site and B-site dopants have been studied to determine how they affect the properties of BNT [9]-[14].

Recently, some investigations have been done on the search for the modifications in the BNT-based systems [15]. To improve the piezoelectric properties, a number of BNT-based solid solutions, such as BNT-Bi$_{0.5}$K$_{0.5}$TiO$_3$ [16], (1 - x - y) Bi$_{0.5}$Na$_{0.5}$TiO$_3$-xBi$_{0.5}$K$_{0.5}$TiO$_3$ [17], BNT-NaNbO$_3$ [18], BNT-Ba-TiO$_3$-Bi$_{0.5}$Li$_{0.5}$TiO$_3$ [19], B$_2$O$_3$Na$_{0.5}$TiO$_3$-SrTiO$_3$-Bi$_{0.5}$Li$_{0.5}$TiO$_3$ [20] and BNT-Bi$_{0.5}$K$_{0.5}$TiO$_3$-BaTiO$_3$ [21], Bi$_{0.5}$Na$_{0.5}$TiO$_3$-Bi$_{0.5}$Li$_{0.5}$TiO$_3$ [22] have been developed and studied intensively [23]. The Bi$_{0.5}$Na$_{0.5}$TiO$_3$-based piezoelectric substituted by Ba$^{2+}$ [24] [25] and the effect of Ba$^{2+}$ in BNT ceramics on dielectric and conductivity properties have been studied [26].

In this report, Raman spectroscopic studies were done on lead-free antimony doped BNT in order to understand the effect of antimony in their local structure and symmetry.

2. Experimental Procedure

Antimony (Sb, x = 0.01%, 0.02% and 0.03%) doped Bi$_{0.5}$Na$_{0.5}$TiO$_3$ compositions were prepared using solid state reaction route. The stoichiometric amount of Bi$_2$O$_3$, Na$_2$CO$_3$, TiO$_2$ and SbO$_2$ (> 99%) were mixed in wet medium (acetone) for 4 h. The mixed powders were calcined at 900$^\circ$C for 4 h by using muffle furnace. Calcined powder were structurally analyzed using X-ray diffraction data which were carried out using X-ray diffractometer with Cu K$_\alpha$ ($\lambda = 1.54056$Å). Fine calcined powder were pressed into cylindrical pellets of 10 mm diameter and 1 - 2 mm thickness under an iso-static pressure of 100 MPa. Polyvinyl alcohol (PVA) was used as a binder. The pellet were sintered at 950$^\circ$C for 4 hours and cooled down to room temperature. Air dried silver past was used for electroding the pellets.

3. Results and Discussion

3.1. Structural Study

Figure 1(a) shows the XRD patterns of Sb (0.0, 0.01, 0.02 and 0.03) doped Bi$_{0.5}$Na$_{0.5}$TiO$_3$ ceramics sintered at 950$^\circ$C for 4 h. All the compositions exhibit a pure perovskite structure and no second phases are observed, which implies that Sb ceramic has diffused into the Bi$_{0.5}$Na$_{0.5}$TiO$_3$ lattices completely. All the reflection peaks of the X-ray profile were indexed and lattice parameters were determined using a least-squares method with the help of a standard computer programme (POWD) [27]. The values of observed (d$_{obs}$) and calculated (d$_{cal}$) interplanar spacing, (hkI) indexing and intensity are shown in Table 1. Good agreement between the observed and
Figure 1. (a) X-ray diffraction patterns of Sb doped BNT ceramics of different compositions; (b) X-ray diffraction patterns of Sb doped BNT ceramics of different compositions in the $2\theta$ range 42 - 50 degree.

calculated inter-planar spacing (d-values), suggests that the compositions are stabilized in rhombohedral phase. The unit cell is selected for which $\Sigma \Delta d = \Delta(d_{\text{obs}} - d_{\text{cal}})$ is minimum. It can be seen from Figure 1 that the prepared compositions have pure phase without any detectable impurity phases. The lattice constants obtained for different compositions are shown in table 1 for rhombohedral and hexagonal unit cells. The estimated lattice parameters are very close to those obtained in earlier reports [28] [29] (JCPDF No-36-0340). Also Figure 1(b) shows the XRD patterns of the ceramics in the $2\theta$ range of 42 - 50 degree. A distinct 002/200 peak splitting appears when doping percentage changes from 0.02 to 0.03, referring to a hexagonal symmetry. To characterize the phase compositions in a more quantitative way, the XRD patterns of the MPB compositions in the $2\theta$ ranges of 46˚ - 48˚ were fitted as shown in Figure 2. The data shows the Lorentzian deconvolution of the 002 and 200 peaks of the tetragonal phase and the 202 peak of the rhombohedral phase. These results suggest that the rhom-
bohedral-hexagonal morphotropic phase boundary (MPB) appears in ceramic near to doping level at 0.03% Sb content.

3.2. Raman Spectroscopic Analysis

Figure 3 represents the Raman spectra of pure BNT and Sb doped BNT with different percentage. There are only five Raman-active modes observed in the range from 100 to 1000 cm\(^{-1}\) in agreement with earlier report [30] [31]. BNT ceramics with rhombohedral structure presents 13 Raman-active modes (\(\Gamma_{\text{Raman}} = 4A_1 + 9E\)) due to the disorder in A-site related to distorted octahedral [BiO\(_6\)] and [NaO\(_6\)] clusters [32]. The first Raman active \(A\_1\) (TO\(_1\)) mode at around (144 cm\(^{-1}\)) is related to distorted octahedral [BiO\(_6\)] and [NaO\(_6\)] clusters. The second Raman active \(E\) (TO\(_2\)) mode was observed in the regions of 276 cm\(^{-1}\) which is assigned to stretching arising from the bonds due to presence of octahedral [TiO\(_6\)] clusters at short-range.

The third Raman-active (LO\(_3\)) mode is related to short-range electrostatic forces associated with the lattice iconicity [33]. The (TO\(_3\)) mode situated at around 541 cm\(^{-1}\) may be due to the (O-Ti-O) stretching symmetric vibrations of the octahedral [TiO\(_6\)] clusters [34]. The (LO\(_3\)) mode found at 813 cm\(^{-1}\) is due to the presence of the sites within the rhombohedral lattice pre containing octahedral distorted [TiO\(_6\)] clusters [35]. There is no significant change in the spectra for the prepared compositions. For better observation of the Raman spectra of BNT pure and Sb doped BNT (Sb = 0.03%) along with the curves fitted to individual peaks are shown in Figure 4.

The spectra of BNT (Sb = 0.03%) shows additional peaks around 151, 281, 585 and 853 cm\(^{-1}\) compared to the peaks observed in BNT. The occurrence of these bands splitting may be due to structural change at doping level 0.03% of Sb, which are well in line with the studies of XRD phase analysis. However, from Figure 3 it is possible to detect that all the Raman peaks are very broad in BNT and Sb doped BNT ceramics. It is believed that this behaviour is due to the presence of the disorder structural or distorted octahedral [TiO\(_6\)] clusters at short-range and the overlapping of Raman modes due to the lattice anharmonicity.

For closer investigation, the variation of full width of half maximum (FWHM) and intensity of individual peaks are plotted in Figure 5(a) and Figure 5(b). The mode intensity and FWHM undergo slope change at Sb = 0.03. The variation of intensity and FWHM of all peaks shows a similar type of anomaly at Sb = 0.03. On the basis of these considerations, it is possible to conclude that the rhombohedral-tetragonal phase co-exists at \(x = 0.03\) which is also observed in the XRD results.

4. Conclusion

Pure and antimony doped BNT electro ceramics were successfully synthesized by a conventional solid state reaction route. X-ray diffraction analysis showed that a probable structural change at the 0.03% Sb doped with the BNT. It may be possible that a morphotropic phase boundary (MPB) exists around \(x = 0.03\). Analysis of
Figure 3. Raman spectra of Sb doped BNT ceramic with different compositions.

Figure 4. Raman spectra of BNT Black line is the experimental data and green lines are the fitting curve versus Sb concentration. (a) For pure BNT while (b) for BNT with 0.03% Sb.

Figure 5. Variation of the FWHM and intensity of different modes in the Raman spectra versus Sb-concentration is shown in figure (a) and (b) respectively.
peak positions, widths and intensities of Raman spectroscopy study also confirmed the existence of structural change around $x = 0.03$ composition.
