ABSTRACT

The mass spectrum of the D wave mesons is considered in the framework of relativistic harmonic model (RHM). The full Hamiltonian used in the investigation has the Lorentz scalar plus a vector harmonic-oscillator potential, the confined-one-gluon-exchange potential (COGEP) and the instanton-induced quark-antiquark interaction (III). A good agreement between calculated D wave meson masses with experimental D wave meson masses is obtained. The respective role of III and COGEP in the D wave meson spectrum is discussed.

Keywords: Quark Model; Confined-One-Gluon-Exchange Potential; Instanton Induced Interaction; D Wave Meson Spectra

1. INTRODUCTION

The Quantum Chromodynamics (QCD), the theory of strong interactions, is not exactly solvable in the non-perturbative regime which is required to obtain the physical properties of the hadrons. Hence various approximation methods like lattice gauge theories are employed to solve QCD in the non-perturbative regime. In the constituent quark model, conventional mesons are bound states of a spin ½ quark and spin ½ antiquark bound by a phenomenological potential. The phenomenological models developed to explain the observed properties of mesons are either non-relativistic quark models (NRQM) with suitably chosen potential or relativistic models where the interaction is treated perturbatively [1-3]. In most of the works that use NRQM, it is assumed that the quark interaction is dominated by a linear or quadratic confinement potential and is supplemented by a short range potential stemming from the one-gluon exchange mechanism. The Hamiltonian of these quark models usually contains three main ingredients: the kinetic energy, the confinement potential and a hyperfine interaction term, which has often been taken as an effective one-gluon-exchange potential (OGEP) [4]. Other types of hyperfine interaction like Instanton-Induced Interaction (III) deduced by a non-relativistic reduction of the ‘t Hooft interaction [5-12] have also been introduced in the literature.

The success of the NRQM in describing the hadron spectrum is somewhat paradoxical, as light quarks should in principle not obey a non-relativistic dynamics. This paradox has been avoided in many works based on the constituent quark models by using for the kinetic energy term of the Hamiltonian a semi-relativistic or relativistic expression [9-12]. Even in the existing relativistic models though the effect of confinement of quarks has been taken into account, the effect of confinement of gluons has not been taken into account [13-15]. Therefore in our present work, we have investigated the effect of exchange of confinement of gluons on the masses of light D wave mesons and their radially excited states in the framework of RHM with III [6,11-12,16]. The essential new ingredient in our investigation of the light D wave mesonic states is to take into account the confinement of gluons in addition to the confinement of quarks. In the existing quark models, Fermi-Breit interaction which gives rise to π-ρ and N-Δ splitting is treated as perturbation. The OGEP being attractive for π, and for a nucleon a naïve perturbative treatment of one gluon hyperfine interaction is incorrect and hence one obtains a high value for the pion mass. This leads to further renormalization of strength of interaction for a better fit. Also, the most prominent flaw of NRQM is the neglect of relativistic effects and gluon dynamics. In our present work, for the confinement of quarks we are making use of the RHM which has been successful in explaining the properties of light hadrons. For the confinement of gluons, we have made use of the current confinement model (CCM) which was developed in the spirit of the RHM [13-15]. The CCM has been quite successful in describing the glue-ball spectra. The confined gluon...
propagators (CGP) are derived in CCM. Using CGP we have obtained confined one gluon exchange potential (COGEP). The full Hamiltonian used in the investigation has Lorentz scalar plus a vector harmonic-oscillator potential, in addition to two-body COGEP and III. In our present work we are extending the model to study D wave light meson spectra. In our present work, the total mass of the meson is obtained by calculating the energy eigen values of the Hamiltonian in the harmonic oscillator basis spanned over a space extending up to the radial quantum number \( n_{\text{max}} = 4 \). The masses of \( D \) wave mesons are obtained after diagonalising for various values of \( n_{\text{max}} \).

In Section 2, we review the RHM and CCM models and give a brief description of the CGP, COGEP and III. We also discuss the parameters involved in our model. The results of the calculations are presented in Section 3. Conclusions are given in Section 4.

2. THE MODEL

In RHM, quarks in a hadron are confined through the action of a Lorentz scalar plus a vector harmonic-oscillator potential [13-15].

\[
V_{\text{conf}}(r) = \frac{1}{2}(1 + \gamma_0)A^2 r^2 + M \tag{1}
\]

where \( \gamma_0 \) is the Dirac matrix:

\[
\gamma_0 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{2}
\]

\( M \) is the quark mass and \( A^2 \) is the confinement strength. They have a different value for each quark flavour. In RHM, the confined single quark wave function \( \psi \) is given by:

\[
\psi = N \begin{pmatrix} \phi \\ \mathbf{P} \end{pmatrix} \tag{3}
\]

with the normalization

\[
N = \frac{2(E + M)}{3E + M}. \tag{4}
\]

where \( E \) is an eigenvalue of the single particle Dirac equation with the interaction potential given in (1). The lower component is eliminated by performing the similarity transformation,

\[
U \psi = \phi \tag{5}
\]

where \( U \) is given by,

\[
\frac{1}{N} \begin{pmatrix} 1 & \mathbf{P} \\ \mathbf{P}^T & E + M \end{pmatrix} \begin{pmatrix} \frac{1}{E + M} & -\mathbf{P} \\ \mathbf{P} & 1 \end{pmatrix} \tag{6}
\]

formation operator. With this transformation, the upper component \( \phi \) satisfies the harmonic oscillator wave equation.

\[
\left[ \frac{\mathbf{P}^2}{E + M} + A^2 r^2 \right] \phi = (E - M) \phi \tag{7}
\]

which is like the three dimensional harmonic oscillator equation with an energy-dependent parameter \( \Omega_5^2 \):

\[
\Omega_5 = A(E_s + M)^{1/2}. \tag{8}
\]

The eigenvalue of (7) is given by,

\[
E_s^2 = M^2 + (2n + 1)\Omega_5^2. \tag{9}
\]

Note that Eq.7 can also be derived by eliminating the lower component of the wave function using the Foldy-Wouthuysen transformation as it has been done in [13].

Adding the individual contributions of the quarks, we obtain the total mass of the hadron. The spurious centre of mass (CM) is corrected by using intrinsic operators for the \( \sum r_i^2 \) and \( \sum V_i^2 \) terms appearing in the Hamiltonian. This amounts to just subtracting the CM motion zero point contribution from the \( E_s^2 \) expression. It should be noted that this method is exact for the \( 0S \) state quarks as the CM motion is also in the \( 0S \) state.

The two body quark-antiquark potential is the sum of COGEP and III potential.

\[
V_q(\vec{r}) = V_{\text{COGEP}}(\vec{r}) + V_{\text{III}}(\vec{r}) \tag{10}
\]

COGEP is obtained from the scattering amplitude [3,13-15],

\[
M_i = \frac{g_i^2}{4\pi} \frac{\lambda_i}{2} \psi_i \psi_j D_{ij}^{ab}(q) \frac{\lambda_f}{2} \psi_j, \tag{11}
\]

where, \( \psi_i = \psi_{i_{0}} \), \( \psi_{ij} \) are the wave functions of the quarks in the RHM, \( D_{ij}^{ab} = \partial_{\mu}D_{ij}^{ab} \) are the CCM gluon propagators in momentum representation, \( g_i^2/(4\pi) = \omega_i \) is the quark-gluon coupling constant and \( \lambda_i \) is the color \( SU(3) \) generator of the \( i_{th} \) quark. The details can be found in references [3,13]. Below, we list the expressions for the central, tensor and spin-orbit part of the COGEP.

The central part of COGEP is [3,13-15],

\[
V_{\text{cent}}^{\text{COGEP}}(\vec{r}) = \frac{\alpha_i N_i^4}{4} \frac{\lambda_i}{\lambda_f} \left[ D_{i}(\vec{r}) + \frac{1}{(E + M)^2} \left[ 4\pi \delta^3(\vec{r}) - c^2 r^2 D_{i}(\vec{r}) \right] \right] [1 - 2/3 \mathbf{\sigma}, \mathbf{\sigma}] \tag{12}
\]

To calculate the matrix elements (ME) of COGEP, we have fitted the exact expressions of \( D_b(\vec{r}) \) and \( D_t(\vec{r}) \) by Gaussian functions. It is to be noted that the \( D_b(\vec{r}) \) and \( D_t(\vec{r}) \) are different from the usual Coulombic propagators. However, in the asymptotic limit \( (\vec{r} \to 0) \) they are similar to Coulombic propagators and in the infrared limit \( (\vec{r} \to \infty) \) they fall like Gaussian. In the
above expression the c (fm\(^{-1}\)) gives the range of propagation of gluons and is fitted in CCM [13,14] to obtain the glue ball spectra. The \(D_0(r)\) and \(D_1(r)\) are given by,

\[
D_0(\vec{r}) = \left[ \frac{\alpha_1}{r} + \alpha_2 \right] \exp \left[ -\frac{r^2 c_0^2}{2} \right] ; \quad D_1(\vec{r}) = \frac{\gamma}{r} \exp \left[ -\frac{r^2 c_0^2}{2} \right]
\]

where \(\alpha_1 = 1.035994, \quad \alpha_2 = 2.016150 \text{ fm}^{-1}, \quad c_0 = (3.001453)^{1/2} \text{ fm}^{-1}, \quad \gamma = 0.8639336.\)

And \(c_2 = (4.367436)^{1/2} \text{ fm}^{-1}.\)

Tensor part of COGEP is,

\[
V_{ten}^{COGEP}(\vec{r}_0) = \frac{\alpha_1}{4} \kappa_i \cdot \kappa_j \frac{N^4}{(E + M)^2} \left( \frac{D_0^i(\vec{r}_0) - D_0^j(\vec{r}_0)}{3r} \right) \hat{S}_{ij}
\]

where \(\hat{S}_{ij} = \lfloor 3(\sigma_i \cdot \overrightarrow{r})(\sigma_j \cdot \overrightarrow{r}) - \sigma_i \cdot \sigma_j \rfloor \)

where \(\vec{r} = \vec{r}_1 - \vec{r}_2\) is the unit vector in the direction of \(\vec{r}\).

In the above expression primes and double primes corresponds to first and second derivatives of \(D_0(r)\). The derivatives of \(D_0(r)\) were fitted to Gaussian functions.

\[
D_0^i(\vec{r}_0) = \frac{1}{r} \exp \left[ -\frac{r^2 c_0^2}{2} \right] - \frac{1}{r^2} \gamma \exp \left[ -\frac{r^2 c_0^2}{2} \right]
\]

\[
D_1^i(\vec{r}_0) = \frac{2}{r} \gamma \exp \left[ -\frac{r^2 c_0^2}{2} \right] - \frac{2}{r^2} \exp \left[ -\frac{r^2 c_0^2}{2} \right] + \frac{1}{r} \exp \left[ -\frac{r^2 c_0^2}{2} \right]
\]

The non-central part of III has contributions from both spin-orbit and tensor terms. The spin-orbit contribution comes from relativistic corrections to the central potential of III. It is given by [8-12],

\[
V_{III}^{SO}(\vec{r}_0) = V_{LS}^{SO}(\vec{r}_0) \hat{L} \cdot \hat{S} + V_{LS}^{SO}(\vec{r}_0) \hat{L} \cdot \hat{A}
\]

The first term in Eq.17 is the traditional symmetric spin-orbit term proportional to the operator \(\hat{L} \cdot \hat{S}\). The other term is the anti-symmetric spin-orbit term proportional to \(\hat{L} \cdot \hat{A}\) where \(\hat{A} = -\frac{1}{2}(\sigma_1 - \sigma_2)\).

The functions of Eq.17 are expressed as [8-12],

\[
V_{LS}^{SO}(\vec{r}_0) = \frac{1}{M_J^2} \sum_{s=3}^4 \sum_{j=3}^8 \frac{\exp(-r_0^2/\eta_{s,j}^2)}{(\eta_{s,j} \sqrt{\pi})^3} + \frac{1}{M_{LM}^2} \sum_{s=5}^8 \sum_{j=5}^8 \frac{\exp(-r_0^2/\eta_{s,j}^2)}{(\eta_{s,j} \sqrt{\pi})^3}
\]

The term \(V_{LS}(\vec{r})\) is responsible for the spitting of the \(^3L_J\) states with \(J = L - 1, L, L + 1\). With such a term \(L\) is still good quantum numbers but S is not. The term \(V_{LS}(\vec{r})\) which couples states \(^3L_{j=4}\) and \(^3L_{j=4}\). Due to the mass dependence in Eq.19, it is clear that this term is inoperative when the quarks are identical. In practice the antisymmetric spin orbit term is important.
only in the K-sector. The terms $\kappa_i$ and $\eta_i$ are free parameters in the theory [12]. $M_i$ corresponds to the mass of the strange quark (s) and $M_j$ corresponds to mass of (u/d) quark. This term accounts for the splitting between 1$^D_2$ and 1$^D_1$ states in the K sector.

The tensor interaction of III is [12],

$$V_{\text{ten}}^{III}(r_0) = \frac{\hat{S}_{\eta}(r_0)}{M_i M_j} \sum_{i=1}^{8} \kappa_i \eta_i \exp\left(-\frac{r_0^2}{\eta_i^2}\right)$$  \hspace{1cm} (20)

with the tensor interaction, $L$ is no longer a good quantum number since this term couples the states $^3L_{J-L+1}$ and $^3(L+2)_{J-L+1}$.

The parameters of the RHM are the masses of the quarks, $M_u = M_d$ and $M_s$, the respective confinement strengths, $A_u = A_d$, $A_s$, and the oscillator size parameter $b_0 = (1/\Omega_n)$. They have been chosen to reproduce various nucleon properties: the root mean square charge radius, the magnetic moment and the ratio of the axial coupling to the vector coupling [13]. The confinement strength $A_{u,d}$ is fixed by the stability condition for the nucleon masses.

The tensor interaction of III has 12 additional strength and size parameters $\kappa_i$ and $\eta_i$'s (in Eqns. 18-20) respectively. The values of $\kappa_i$'s and $\eta_i$'s are fixed from S and P wave meson spectroscopy [12,16] and are listed in Table 1 and 2.

3. RESULTS AND DISCUSSIONS

To calculate the meson masses, the product of quark-antiquark oscillator wave functions is expressed in terms of oscillator wave functions corresponding to the relative and CM coordinates. The oscillator quantum number for the CM wave functions is restricted to $N_{CM} = 0$. The Hilbert space of relative wave functions is truncated at radial quantum number $n_{max} = 4$. The Hamiltonian matrix is constructed for each meson separately in the basis states of $\{N_{CM} = 0, L_{CM} = 0; ^{2S+1}L_J\}$ and diagonalised.

We have obtained the D wave meson spectra using the model described above. The masses of the singlet and triplet D wave mesons after diagonalisation in harmonic oscillator basis with $n_{max} = 4$ are listed in Tables 3 and 4 respectively. The results show that III potential along with COGEP is necessary to obtain the meson mass spectra. If COGEP is taken as the only source of hyperfine splitting, the value of $\alpha_i$ necessary to reproduce the hadrons spectrum is generally much larger than one; this leads to a large spin-orbit interaction, which destroys the overall fit to the spectrum. The inclusion of III diminishes the relative importance of COGEP for the hyperfine splitting. The important role played by III in obtaining the masses of these mesons can be well understood by examining the Table 6. In Table 6, we have given the calculated masses of triplet D wave mesons.

The parameters associated with the strange quark $M_s$ and $A_s^2$ have been fitted in order to reproduce the magnetic moments of the strange baryons, according to the procedure described in [16]. The $\alpha_s$ of COGEP is fixed from S wave meson spectroscopy [16]. The value of $\alpha_s$ turns out to be 0.2 for D wave mesons, which is compatible with the perturbative treatment. Among the non central parts of the potential, the hyperfine terms of III has 12 additional strength and size parameters $\kappa_i$'s and $\eta_i$'s (in Eqns. 18-20) respectively. We note that the $\kappa_i$ values can have both positive and negative values [8-12]. The values of the III parameters $\kappa_i$'s and $\eta_i$'s are fixed from S and P wave meson spectroscopy [12,16] and are listed in Table 1 and 2.

due to the large difference in tensor part of III potential. The tensor III potential is attractive for K$^*$ (1680) but is repulsive for K$_2$ (1820) [17]. In case of 1$^3$D$_1$ mesons the contribution due to spin-orbit part of III potential is dominant compared to that of tensor part which is repulsive. From Tables 3 and 4, it is clear that the calculated meson masses are in good agreement with the experimental masses [18].

4. CONCLUSIONS

We have investigated the effect of the III on the masses of the D wave mesons in the framework of RHM. We have shown that the computation of the masses using only COGEP is inadequate. The contribution of the III is found to be significant. To obtain the masses of D wave mesons, 5x5 Hamiltonian matrix was diagonalised. The contribution from the tensor and spin-orbit part of the III is found to be significant in case of triplet D wave mesons. To obtain the physical masses of the mesons in the K sector it is necessary to include the anti-symmetric part of III. There is a good agreement between the calculated and experimental masses of D wave mesons. To enhance the performance of the model, there is a need to make a global chi-square fit of the parameters and also to test different wave functions which would ultimately give better result. Also, the model has to be tested to calculate the leptonic and radiative decay widths. Work in this direction is in progress.

5. ACKNOWLEDGEMENTS

One of the authors (APM) is grateful to the DST, India, for granting the JRF. The other author (KBV) acknowledges the DST for funding the project (Sanction No. SR/S2/HEP-14/2006) and the fruitful discussion he had with Y.L. Ma of IHEP, Beijing.
