Abstract

In this work, we present final solving Millennium Prize Problems formulated by Clay Math. Inst., Cambridge. A new uniform time estimation of the Cauchy problem solution for the Navier-Stokes equations is provided. We also describe the loss of smoothness of classical solutions for the Navier-Stokes equations.

Keywords

1. Introduction

In this work, we present final solving Millennium Prize Problems formulated by Clay Math. Inst., Cambridge in [1]. Before this work, we already had first results in [2]-[4]. The Navier-Stokes existence and smoothness problem concerns the mathematical properties of solutions to the Navier-Stokes equations. These equations describe the motion of a fluid in space. Solutions to the Navier-Stokes equations are used in many practical applications. However, theoretical understanding of the solutions to these equations is incomplete. In particular, solutions of the Navier-Stokes equations often include turbulence, which remains one of the greatest unsolved problems in physics. Even much more basic properties of the solutions to Navier-Stokes have never been proven. For the three-dimensional system of equations, and given some initial conditions, mathematicians have not yet proved that smooth solutions always exist, or that if they do exist, they have bounded energy per unit mass. This is called the Navier-Stokes existence and smoothness problem. Since understanding the Navier-Stokes equations is considered to be the first step to understanding the elusive phenomenon of turbulence, the Clay Mathematics Institute in May 2000 made this problem one of its seven Millennium Prize problems in mathematics. In this paper,
we introduce important explanations results presented in the previous studies in [2]-[4]. We therefore reiterate the basic provisions of the preceding articles to clarify understanding them. First, we consider some ideas for the potential in the inverse scattering problem, and this is then used to estimate of solutions of the Cauchy problem for the Navier-Stokes equations. A similar approach has been developed for one-dimensional nonlinear equations [5]-[8], but to date, there have been no results for the inverse scattering problem for three-dimensional nonlinear equations. This is primarily due to difficulties in solving the three-dimensional inverse scattering problem. This paper is organized as follows: first, we study the inverse scattering problem, resulting in a formula for the scattering potential. Furthermore, with the use of this potential, we obtain uniform time estimates in time of solutions of the Navier-Stokes equations, which suggest the global solvability of the Cauchy problem for the Navier-Stokes equations. Essentially, the present study expands the results for one-dimensional nonlinear equations with inverse scattering methods to multi-dimensional cases. In our opinion, the main achievement is a relatively unchanged projection onto the space of the continuous spectrum for the solution of nonlinear equations that allows focusing only on the behavior associated with the decomposition of the solutions to the discrete spectrum. In the absence of a discrete spectrum, we obtain estimations for the maximum potential in the weaker norms, compared with the norms for Sobolev’s spaces.

Consider the operators $H = -\Delta + q(x)$ and $H_0 = -\Delta$, defined in the dense set $W^2_2(\mathbb{R}^3)$ in the space $L_2(\mathbb{R}^3)$; let $q$ be a bounded fast-decreasing function. The operator $H$ is called the Schrödinger’s operator. We consider the three-dimensional inverse scattering problem for the Schrödinger’s operator: the scattering potential must be reconstructed from the scattering amplitude. This problem has been studied by a number of researchers [9] [11] [12] and references therein.

2. Results

Consider Schrödinger’s equation:

$$-\Delta \Psi + q(x)\Psi = k^2 \Psi, \quad k \in \mathbb{C}. \quad (1)$$

Let $\Psi_+(k,\theta,x)$ be a solution of (1) with the following asymptotic behavior:

$$\Psi_+(k,\theta,x) = e^{ikx} + \frac{e^{ik\theta}}{|x|} A(k,\theta',\theta) + o\left(\frac{1}{|x|}\right), \quad |x| \to \infty \quad (2)$$

where $A(k,\theta',\theta)$ is the scattering amplitude and $\theta' = x/|x|$, $\theta \in S^2$ for $k \in \mathbb{C}^+ = \{\text{Im} k \geq 0\}$

$$A(k,\theta',\theta) = \frac{1}{4\pi} \int_{\mathbb{R}^3} q(x) \Psi_+(k,\theta,x) e^{-i\theta'x} dx. \quad (3)$$

Let us also denote the solution $\Psi_-(k,\theta,x)$ for $k \in \mathbb{C}^- = \{\text{Im} k < 0\}$ as $\Psi_-(k,\theta,x) = \Psi_+(k,\theta,-x)$ As is well known [9]:

$$\Psi_+(k,\theta,x) - \Psi_-(k,\theta,x) = -\frac{k}{4\pi} \int_{S^2} A(k,\theta',\theta) \Psi_-(k,\theta',x) d\theta', \quad k \in \mathbb{R}. \quad (4)$$

This equation is the key to solving the inverse scattering problem, and was first used by Newton [10] [11] and Somersalo et al. [12].

Equation (4) is equivalent to the following:

$$\Psi_+ = S \Psi_- \quad (5)$$

where $S$ is a scattering operator with kernel $S(k,l) = \int_{\mathbb{R}^3} \Psi_+(k,x) \Psi_-^*(l,x) dx$.

The following theorem was stated in [9]:

Theorem 1. (The energy and momentum conservation laws) Let $q \in \mathbb{R}$. Then, $SS^* = I$, $S^*S = I$, where $I$ is a unitary operator.

Definition 1. The set of measurable functions $\mathfrak{A}$ with norm defined by $\|q\|_{\mathfrak{A}} = \int_{\mathbb{R}^6} \frac{q(x)q(y)}{|x-y|^2} dxdy$ is recognized as being of Rollnik class.
As shown in [13], \( \Psi_j(k,x) \) is an orthonormal system of \( H \) eigenfunctions for the continuous spectrum. In addition to the continuous spectrum there are a finite number \( N \) of \( H \) negative eigenvalues, designated as \(-E_j\), with corresponding normalized eigenfunctions

\[
\psi_j(x,-E_j) \quad (j = 1, N)
\]

where

\[
\psi_j(x,-E_j) \in L^2(R^3).
\]

We present Povzner’s results [13] below:

Theorem 2. (Completeness) For both an arbitrary \( f \in L^2(R^3) \) and for \( H \) eigenfunctions, Parseval’s identity is valid.

\[
\|f\|_2^2 = \left(\sum_{j=1}^N \int_{R^3} |\psi_j(x,-E_j)|^2 \psi_j^*(x,-E_j) f(x) \ dx \right) + \left(\sum_{j=1}^N \int_{R^3} |\psi_j(x,-E_j)|^2 \psi_j^*(x,-E_j) p_k \ f(x) \ dx \right)
\]

\[
P_{n,k} f = \sum_{j=1}^N f \psi_j(x,-E_j), \quad P_{n,k} f = \int_0^\infty \int_{R^3} s^2 \tilde{f}(s) \Psi_j(s,\theta,\phi) \ d\theta ds
\]

where \( \tilde{f} \) and \( f_j \) are Fourier coefficients for the continuous and discrete cases.

Theorem 3. (Birman-Schwinger estimation). Let \( q \in \mathbb{R} \). Then, the number of discrete eigenvalues can be estimated as:

\[
N(q) \leq \frac{1}{(4\pi)^2} \int_{R^2} \int_{R^2} q(x)q(y) \left| x-y \right|^2 \ dx \ dy.
\]

This theorem was proved in [14].

Let us introduce the following notation:

\[
NA = \int_{R^2} A(k,\theta,\theta) \ d\theta \quad \text{for} \quad f(k,\theta',x), \quad \text{Df} = \int_{R^2} A(k,\theta,\theta) f(k,\theta',x) \ d\theta'
\]

\[
\phi_0(\sqrt{z},\theta,\phi) = e^{iE_0 z}, \quad \Phi(\sqrt{z},\theta,\phi) = \left( \Psi_j(\sqrt{z},\theta',\phi) - e^{iE_0 z} \right) \Delta
\]

where

\[
\Delta = \prod_{j=1}^N \left( k_i E_j \right) \left( k_i E_j \right).
\]

We define the operators \( T_+ \) and \( T^- \) for \( f \in W^2_2(R) \) as follows:

\[
T_+ f = \frac{1}{2\pi i} \lim_{\text{Im} z \to \infty} \int_{R^+} \frac{f(s)}{s-z} \ ds, \quad \text{Im} z > 0; \quad T_- f = \frac{1}{2\pi i} \lim_{\text{Im} z \to \infty} \int_{R^-} \frac{f(s)}{s-z} \ ds, \quad \text{Im} z < 0
\]

\[
Tf = \frac{1}{2} (T_+ + T_-) f.
\]

Consider the Riemann problem of finding a function \( \Phi \), that is analytic in the complex plane with a cut along the real axis. Values of \( \Phi \) on the upper and lower sides of the cut are denoted \( \Phi_+ \) and \( \Phi_- \) respectively. The following presents the results of [15]:

Lemma 1.

\[
TT = \frac{1}{4} I, \quad TT_+ = \frac{1}{2} T_+, \quad TT_- = -\frac{1}{2} T_+, \quad T_+ = T + \frac{1}{2} I, \quad T_- = T - \frac{1}{2} I
\]

Theorem 4. Let \( q \in \mathbb{R} \), \( g = \Phi_+ - \Phi_- \); then

\[
\Phi_+ = T_+ g.
\]

The proof of the above follows from the classic results for the Riemann problem.

Lemma 2. Let \( q \in \mathbb{R} \), \( g_+ = g\sqrt{z,\theta,\phi} \), \( g_- = g\sqrt{z,-\theta,\phi} \)
Then,
\[ \Psi_+\left(\sqrt{\varepsilon}, \theta, x\right) = \left(T_+g_+, e^{i\int_0^x}\right), \quad \Psi_-\left(\sqrt{\varepsilon}, \theta, x\right) = \left(T_-g_-, e^{i\int_0^x}\right). \]  
(14)

The proof of the above follows from the definitions of \( g, \Phi_+, \Phi_- \) and \( \Psi_+, \Psi_- \).

**Lemma 3.** Let \( q \in \mathbb{R}, A_q = A\left(\sqrt{\varepsilon}, \theta, x\right), A_q = A\left(\sqrt{\varepsilon}, -\theta, x\right) \)

Then,
\[ A(k, \theta', \theta) = T_q\left(A, \Delta = A, A\right). \]  
(15)

The proof of the above again follows from the definitions of \( g, \Phi_+, \Phi_- \) and \( \Psi_+, \Psi_- \).

**Lemma 4.** Let \( q \in \mathbb{R} \). Then,
\[ NA_q = \alpha\left(\Delta = \Delta \right). \]  
(16)

The proof of the above follows from the definitions of \( g, \Phi_+, \Phi_- \) and \( \Psi_+, \Psi_- \) and Theorem 1.

**Lemma 5.** Let \( q \in \mathbb{R} \).

Then,
\[ \left[N \left(A_q \right) \right] = \Delta = \Delta \]  
(17)

The proof of the above follows from the definitions of \( g, \Phi_+, \Phi_- \) and \( \Psi_+, \Psi_- \) and Lemma 4 and dispersions relations for analytics functions.

**Definition 2.** Denote by \( \mathcal{T}_A \) the set of functions \( f(k, \theta, \theta') \) with the norm
\[ \|f\|_{\mathcal{T}_A} = \sup_{\theta, \theta, \theta'} \left( |f| + |f| \right) < \infty. \]

**Definition 3.** Denote by \( \mathcal{R}_{(I-T,D)} \) the set of functions \( g \) such that \( g = (I-T,D) f \), for any \( f \in \mathcal{T}_A \).

**Lemma 6.** Suppose \( \|f\|_{\mathcal{T}_A} < \alpha < 1 \). Then, the operator \( (I-T,D) \), defined on the set \( \mathcal{T}_A \) has an inverse defined on \( \mathcal{R}_{(I-T,D)} \).

The proof of the above follows from the definitions of \( D, T_D \), and the conditions of Lemma 6.

**Lemma 7.** Let \( q \in \mathbb{R} \), and assume that \( (I-T,D) \) exists. Then,
\[ g = T_q g - T_q g, \quad T_q g = (I-T,D)^{-1} T_q D, \quad \Psi_- = \frac{1}{\Delta} (I-T,D)^{-1} T_q D. \]  
(18)

The proof of the above follows from the definitions of \( g, \Phi_+, \Phi_- \) and \( \Psi_+, \Psi_- \) and Equation (4).

**Lemma 8.** Let \( q \in \mathbb{R} \), and assume that \( (I-T,D) \) exists. Then,
\[ \Psi_- = \sum_{n=1}^{\infty} \left( -\frac{1}{\Delta} T \right)^n \Psi_0 + \frac{1}{\Delta} T D + \frac{1}{\Delta} T D + \frac{1}{\Delta} T D + \frac{1}{\Delta} T D + Q_3. \]  
(19)

where \( Q_3 \) represents terms of highest order of \( T \).

The proof. Using
\[ \int_{x}, \Psi_- (x,k) \Psi_- (x,\ell) dx = \delta (k-l), \quad \int_{x}, \phi_0 (x,k) \phi_0 (x,\ell) dx = \delta (k-l) \]
and (18) we get proof.

**Lemma 9.** Let \( q \in \mathbb{R} \). Then,
\[ q = \lim_{i \to \infty} \left[ H_q \Psi_- / \Psi_- \right]. \]  
(20)

The lemma can be proved by substituting \( \Psi_+, \Psi_- \) into Equation (1).

**Lemma 10.** Let \( q \in \mathbb{R} \), and assume that \( (I-T,D) \) exists. Then,
\[ q = \lim_{i \to \infty} \left[ \frac{1}{\Delta} N (I-T,D)^{-1} T_D \phi_0 \right] / \left( \frac{1}{\Delta} N (I-T,D)^{-1} T_D \phi_0 + N \phi_0 \right). \]  
(21)

The proof of the above follows from the definitions of \( N, \Psi_+, \Psi_- \) and Lemma 7.

**Lemma 11.** Let \( q \in \mathcal{R} \). Then \( \|D\| \leq 2 \).

The proof of the above follows from the definition of \( D \) and the unitary nature of \( S \).
Lemma 12. Let \( q \in \mathcal{R} \cap L_2 \left( R^3 \right) \). Then,

\[
E_j^2 \leq \int_{E_j} |q(x)|\psi_j \int_{E_j} \text{dx}
\]

\[
\max_{x} |\psi_j(x)| \leq 2 \left\| \psi_j \right\|_{L_2(\mathcal{R}^3)}.
\]

The proof of the above follows from the definitions of \( E_j^2 \), \( \psi_j \), and (1).

Lemma 13. Let \( q \in \mathcal{R} \cap L_2 \left( R^3 \right) \), and \( \left\| A \right\|_{L_2} < \alpha < 1 \). Then,

\[
\left| \left[ \psi \right| \right|_{L_2} \leq \sum_{i=0}^{\infty} \left( C_0 \left\| N4 \right\|_{L_2} \right)^i.
\]

To prove this result, one should calculate \( \Psi_+^\pm, \Psi_-^\pm \) using (18).

Lemma 14. Let \( q \in \mathcal{R} \cap L_2 \left( R^3 \right) \), and \( \left\| A \right\|_{L_2} < \alpha < 1 \). Then,

\[
\max_{x} |q(x)| \leq \int_{R^3} q(x) e^{j(k-\alpha)x} \text{dx}.
\]

For \( f = f(k, \theta', x) \)

\[
Df = k \int_{R^3} A(k, \theta', x) f(k, \theta', x) d\theta'.
\]

Lemma 15. Let \( q \in \mathcal{R} \cap L_2 \left( R^3 \right) \), and \( \left\| A \right\|_{L_2} < \alpha < 1 \). Then,

\[
\left\| N4 \right\|_{L_2} < C \left\| \right\|_{L_2} \left\| Qq \right\|_{L_2}, \left\| N4 \right\|_{L_2} < C \left\| \right\|_{L_2} \left\| Qq \right\|_{L_2}.
\]

To prove this result, one should calculate \( A \) using Lemma 7.

Lemma 16. Let \( q \in \mathcal{R} \) and \( \max_{x} |q| < \infty \).

Then,

\[
\int_{R^3} \int_{R^3} q(x) q(y) e^{j(x-y)} |x-y|^2 \text{dxdy} \leq C \left( |q|_{L_2} + \max_{x} |q| \right)^2.
\]

A proof of this lemma can be obtained using Plancherel’s theorem.

Lemma 17. Let \( q \in \mathcal{R} \cap L_2 \left( R^3 \right) \) and \( \left\| q \right\|_{L_2} + \max_{x} |q| < \alpha < 1 \).

Then,

\[
\Psi_+^\pm > 1 - \alpha / (1 - \alpha)
\]
To prove this result, one should calculate $\Psi_{|t=0}$.

### 3. Cauchy Problem for the Navier-Stokes Equation

Numerous studies of the Navier-Stokes equations have been devoted to the problem of the smoothness of its solutions. A good overview of these studies is given in [16]-[20]. The spatial differentiability of the solutions is an important factor, this controls their evolution. Obviously, differentiable solutions do not provide an effective description of turbulence. Nevertheless, the global solvability and differentiability of the solutions has not been proven, and therefore the problem of describing turbulence remains open. It is interesting to study the properties of the Fourier transform of solutions of the Navier-Stokes equations. Of particular interest is how they can be used in the description of turbulence, and whether they are differentiable. The differentiability of such Fourier transforms appears to be related to the appearance or disappearance of resonance, as this implies the absence of large energy flows from small to large harmonics, which in turn precludes the appearance of turbulence. Thus, obtaining uniform global estimations of the Fourier transform of solutions of the Navier-Stokes equations means that the principle modeling of complex flows and related calculations will be based on the Fourier transform method. The authors are continuing to research these issues in relation to a numerical weather prediction model; this paper provides a theoretical justification for this approach. Consider the Cauchy problem for the Navier-Stokes equations:

\[
\begin{align*}
q_t - \nu \Delta q + (q, \nabla q) &= -\nabla p + f(x,t), \quad \text{div}q = 0 \\
q|_{t=0} &= q_0(x)
\end{align*}
\]

in the domain $Q_T = T \times (0,T)$, where:

\[
\text{div}q_0 = 0.
\]

The problem defined by (34), (35), (36) has at least one weak solution $(q, p)$ in the so-called Leray-Hopf class [16].

The following results have been proved [17]:

**Theorem 5.** If

\[
q_0 \in W^2_0(R^3), \quad f \in L_2(Q_T)
\]

there is a single generalized solution of (34), (35), (36) in the domain $Q_{T_1}$, $T_1 \in [0,T]$, satisfying the following conditions:

\[
q_t, \nabla^2 q, \nabla p \in L(Q_{T_1}).
\]

Note that $T_1$ depends on $q_0$ and $f$.

**Lemma 18.** Let $q_0 \in W^2_0(R^3), f \in L_2(Q_T)$. Then,

\[
\sup_{\partial\Omega \times T} \left\| \frac{\partial}{\partial t} \right\|_{L^2(\Omega)} + \int_\Omega [\nabla q]_{L^2(\Omega)}^2 \, d\tau \leq \|q_0\|_{L^2(\Omega)}^2 + \|f\|_{L_2(\partial\Omega)}^2.
\]

Our goal is to provide global estimations for the Fourier transforms of the derivatives of the solutions to the Navier-Stokes Equations (34)-(36) without requiring the initial velocity and force to be small. We obtain the following uniform time estimation.

**Statement 1.** The solution of (34), (35), (36) according to Theorem 5 satisfies:

\[
\tilde{q} = \tilde{q}_0 + \int_{\Omega} e^{-\Phi(t_1-x)} \left( [(q\nabla)q] + \tilde{F} \right) \, d\tau
\]

where $F = -\nabla p + f$.

This follows from the definition of the Fourier transform and the theory of linear differential equations.

**Statement 2.** The solution of (34), (35), (36) satisfies:
\[ p = \sum_{ij} \frac{k_i k_j}{|k_i|^2} q_j \tilde{q}_i + i \sum_{ij} \frac{k_i}{|k_i|^2} \tilde{f}_i \]  

(41)

and the following estimations:

\[ \|p\|_{L_2(x')} \leq 3 \|q\|_{L_2(x')} \|q\|_{L_2(x')} \]

(42)

\[ \|\nabla p\|_{L_2(x')} \leq \frac{|q|}{|k|} + \frac{|\tilde{f}|}{|k|} + \frac{1}{|k|} \|\nabla \tilde{f}\| + 3 |\nabla q|^2 \]

(43)

This expression for \( p \) is obtained using div and the Fourier transform presentation.

Lemma 19. The solution of (34), (35), (36) in Theorem 5 satisfies the following inequalities:

\[ \sup_{0 \leq \tau \leq T} \|Qq\|_{L_2(x')} + \int_0^T |k^2 Qq|_{L_2(x')} \, d\tau \leq \sup_{0 \leq \tau \leq T} \|Qq\|_{L_2(x')} + \|Q\|_{L_2(\Omega_T)} \]

(44)

Proof this follows from the a priori estimation of Lemma18 and conditions of Lemma 19.

Lemma 20. Let \( Qq \in W^{2}_0 (\Omega_T), f \in L_2(\Omega_T) \) Then, the solution of (34), (35), (36) in Theorem 5 satisfies 2 the following inequalities:

\[ \sup_{0 \leq \tau \leq T} \|Qq\|_{L_2(x')} + \int_0^T \|k^2 Qq\|_{L_2(x')} \, d\tau \leq \sup_{0 \leq \tau \leq T} \|Qq\|_{L_2(x')} + \|Q\|_{L_2(\Omega_T)} \]

(45)

Proof this follows from the a priori estimation of Lemma18 and conditions of Lemma 18 and Lemma 20.

Lemma 21. The solution of (34), (35), (36) in Theorem 5 satisfies the following inequalities:

\[ \int_{x'} |x||q|^2 \, dx + \int_{x'} |x|^2 |\nabla q|^2 \, dx \leq \text{const} \]

(46)

or

\[ \|q\|_{L^2(x')} + \int_{x'} \|k^2 q\|_{L^2(x')} \, dx \leq \text{const} \]

(47)

Proof this follows from the a priori estimation of Lemma18, conditions of Lemma 19, the Navier-Stokes equations.

Lemma 22. The solution of (34), (35), (36) satisfies the following inequalities:

\[ \max_k |q| \leq \max_k |\tilde{q}| + \frac{T}{2} \sup_{0 \leq \tau \leq T} \|q\|_{L^2(x')} + \int_0^T \|\nabla q\|_{L^2(x')} \, d\tau \]

(48)

\[ \max_k |\nabla q| \leq \max_k |\nabla \tilde{q}| + \frac{T}{2} \sup_{0 \leq \tau \leq T} \|\nabla q\|_{L^2(x')} + \int_0^T \int_{x'} |k|^2 \|\nabla q\|_{L^2(x')} \, dk \, d\tau \]

(49)

\[ \max_k |\nabla^2 q| \leq \max_k |\nabla^2 \tilde{q}| + \frac{T}{2} \sup_{0 \leq \tau \leq T} \|\nabla^2 q\|_{L^2(x')} + \int_0^T \int_{x'} |k|^2 \|\nabla^2 q\|_{L^2(x')} \, dk \, d\tau \]

(50)

Proof this follows from the a priori estimation of Lemma18, conditions of Lemma 22, the Navier-Stokes equations.

Lemma 23. The solution of (34), (35), (36) according to Theorem 5 satisfies \( C_i \leq \text{const}, \quad (i = 0, 2, 4) \), where:

\[ C_0 = \int_0^T |F_1|^2 \, d\tau, \quad F_1 = (q, \nabla) \tilde{q} + \nabla, \quad C_2 = \int_0^T |\nabla F_1|^2 \, d\tau, \quad C_4 = \int_0^T |\nabla^2 F_1|^2 \, d\tau. \]

(51)

Proof this follows from the a priori estimation of Lemma18, the Navier-Stokes equations.

Lemma 24. Weak solution of problem (34), (35), (36) from Theorem 5 satisfies the following inequalities:

\[ |NQq| \leq zM_1, \quad \left| \frac{\partial NQq}{\partial z} \right| \leq zM_2, \quad \left| \frac{\partial^2 NQq}{\partial z^2} \right| \leq zM_3 \]

where \( M_1, M_2, M_3 \) are limited.
Let us prove the first estimate. These inequalities
\[ \left| Qq(z,t) \right| \leq \frac{1}{2} \int_0^t \int_0^{t_1} q(z(e_k,e_e),t) \, \, \, dt \leq 2\pi \max_{\lambda} |\tilde{q}| \leq zM_1 \]
where \( M_1 = \text{const.} \).

Proof: Now this follows from the a priori estimation of Lemma 18, conditions of Lemma 24, the Navier-Stokes equations.

The rest of estimates are proved similarly.

Lemma 25. Suppose that \( q \in \mathbb{R} \) and \( \max_{\lambda} |\tilde{q}| < \infty \)
Then,
\[ \int_\mu \int_\nu \frac{q(e)q(y)}{|x-y|} \, dx \, dy \leq C \left( |\tilde{q}|_{L_2} + \max_{\lambda} |\tilde{q}| \right)^2. \]

Proof. Using Plansherel’s theorem, we get the statement of the lemma.

This proves Lemma 25.

Lemma 26. Weak solution of problem (34), (35), (36) from Theorem 5 satisfies the following inequalities
\[ \left| Qq \right| \leq |Qq_0| + \left( \frac{1}{2v} \right) \frac{C_0^2}{z|e_k-e_e|} \]
where
\[ C_0 = \int_0^t \left| \tilde{F}_1 \right| \, d\tau, \quad F_1 = (q,V)q + F. \]

Proof. From (40) we get
\[ \left| Qq \right| \leq |Qq_0| + \left| \int_0^t e^{-v^2} \tilde{h} \tilde{F}_1(z(e_k-e_e),\tau) \, d\tau \right| \]
where
\[ F_1 = (q,V)q + F. \]

Using the notation
\[ I = \left| \int_0^t e^{-v^2} \tilde{h} \tilde{F}_1(z(e_k-e_e),\tau) \, d\tau \right| \]
taking into account Holder’s inequality in \( I \) we obtain:
\[ I \leq \left\{ \int_0^t e^{-v^2} \tilde{h} \tilde{F}_1(z(e_k-e_e),\tau) \, d\tau \right\}^\frac{1}{p} \left( \int_0^t \left| \tilde{F}_1 \right|^p \, d\tau \right)^\frac{1}{q} \]
where \( p \) and \( q \) satisfies the equality \( 1/p + 1/q = 1 \). Suppose \( p = q = 2 \). Then
\[ I \leq \left( \frac{1}{2v} \right) \left( \int_0^t \left| \tilde{F}_1 \right|^2 \, d\tau \right)^\frac{1}{2}. \]

Taking into consideration the estimate \( I \) in (53), we obtain the statement of the lemma.

This proves Lemma 26.

Lemma 27. Weak solution of problem (34), (35), (36) from Theorem 5 satisfies the following inequalities
\[ \left| \frac{\partial Qq}{\partial z} \right| \leq \left| \frac{\partial Qq_0}{\partial z} \right| + 4\alpha \left( \frac{1}{2v} \right) \frac{C_0^2}{z^2|e_k-e_e|} + \left( \frac{1}{2v} \right) \frac{C_0^2}{z^2|e_k-e_e|}, \]where \( C_2 = \int_0^t \left| \frac{\partial \tilde{F}_1}{\partial z} \right|^2 \, d\tau. \)
Proof. The underwritten inequalities follows from representation (40)

\[
\left| \frac{\partial Q}{\partial z} \right| \leq \left| \frac{\partial Q_0}{\partial z} \right| + 2vz|e_k - e_{x_k}| \int_0^t (t - \tau) e^{-v\tau} H_{k-e_{x_k}} \tilde{F}_1(z(e_k - e_{x_k}), \tau) \, d\tau
\]

\[
+ \left| \int_0^t e^{-v\tau} H_{e_{x_k}-e_k} \frac{\partial \tilde{F}_1}{\partial z}(z(e_k - e_{x_k}), \tau) \, d\tau \right|
\]

Let us introduce the following denotation

\[
I_1 = 2vz|e_k - e_{x_k}| \int_0^t (t - \tau) e^{-v\tau} H_{k-e_{x_k}} \tilde{F}_1(z(e_k - e_{x_k}), \tau) \, d\tau
\]

\[
I_2 = \left| \int_0^t e^{-v\tau} H_{e_{x_k}-e_k} \frac{\partial \tilde{F}_1}{\partial z}(z(e_k - e_{x_k}), \tau) \, d\tau \right|
\]

then

\[
\left| \frac{\partial Q}{\partial z} \right| \leq \left| \frac{\partial Q_0}{\partial z} \right| + I_1 + I_2.
\]

Estimate \( I_1 \) by means of

\[
\sup_i \left| e^{-v} \right| < \alpha
\]

where \( m > 0 \) we obtain

\[
I_1 \leq \frac{4\alpha}{z} \left| \int_0^t e^{-v\tau} H_{k-e_{x_k}} \tilde{F}_1(z(e_k - e_{x_k}), \tau) \, d\tau \right|
\]

On applying Holder’s inequality, we get

\[
I_1 \leq \frac{4\alpha}{z} \left( \int_0^t e^{-v\tau} H_{k-e_{x_k}} \tilde{F}_1 \, d\tau \right)^{\frac{1}{p}} \left( \int_0^t \left| \tilde{F}_1 \right|^q \, d\tau \right)^{\frac{1}{q}}
\]

where \( p, q \) satisfies the equality \( 1/p + 1/q = 1 \).

For \( p = q = 2 \) we have

\[
I_1 \leq \frac{4\alpha}{z} \left( \int_0^t e^{-v\tau} H_{k-e_{x_k}} \tilde{F}_1 \, d\tau \right)^2 \frac{1}{z^2} \frac{C_2^\frac{1}{q}}{|e_{x_k} - e_k|}
\]

\[
I_2 \leq \frac{1}{2v} \left( \int_0^t e^{-v\tau} H_{k-e_{x_k}} \tilde{F}_1 \, d\tau \right)^2 \frac{C_2^\frac{1}{q}}{|e_{x_k} - e_k|}
\]

\[
C_2 = \int_0^t \left| \frac{\partial \tilde{F}_1}{\partial z} \right|^2 \, d\tau.
\]

Inserting \( I_1, I_2 \) in to

\[
\left| \frac{\partial Q}{\partial z} \right|
\]

we obtain the statement of the lemma.

This completes the proof of Lemma 27.

Lemma 28. Weak solution of problem (34), (35), (36) from Theorem 5 satisfies the following inequalities

\[
|\mathcal{N}Q_0| \leq C, \quad |\mathcal{N}Q_0| \leq C, \quad |Q_0| \leq C, \quad |Q_0^2| \leq C, \quad |\mathcal{N}Q_0| \leq C, \quad |\mathcal{N}Q_0| \leq C
\]

where \( C = \text{const} \),

Lemma 25. Let \( q \in \mathcal{R} \) and

\[
\max_k |q| < \infty.
\]

Then,
\[ N(q) \leq \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \frac{q(x)q(y)}{|x-y|^2} \, dx \, dy \leq C \left( |q|_{L_2} + \max |q| \right)^2. \]  

(56)

A proof of this lemma can be obtained using Plancherel’s theorem.

We now obtain uniform time estimations for Rollnik’s norms of the solutions of (34), (35), (36). The following (and main) goal is to obtain the same estimations for \( \max |q| \) —velocity components of the Cauchy problem for the Navier-Stokes equations.

Let’s consider the influence of the following large scale transformations in Navier-Stokes’ equation on

\[ K = \frac{v^2}{v^2 - 4\pi CC_0^2}, \quad t' = tA, \quad v' = \frac{v}{A}, \quad F'_0 = \frac{F_0}{A^2}. \]

Statement 3. Let

\[ A = \frac{4}{v^3 (CC_0 + 1)^2}, \quad \text{then} \quad K \leq \frac{8}{7}. \]

Proof. By the definitions \( C \) and \( C_0 \) we have

\[ K = \left( \frac{v}{A} \right)^{\frac{1}{2}} \left( \frac{v}{A} \right)^{\frac{1}{2}} - \frac{4\pi CC_0}{A^2} \right)^{-1} = \frac{1}{v^2 - \frac{4\pi CC_0}{A^2}} \left( \frac{1}{v^2 - \frac{4\pi CC_0}{A^2}} \right)^{-1} < \frac{8}{7}. \]

This proves Statement 3.

Theorem 6. Let

\[ q_0 \in W^2_2 \left( \mathbb{R}^3 \right), \quad \nabla^2 q_0 \in L_2 \left( \mathbb{R}^3 \right), \quad f \in L_2 \left( Q_T \right), \quad \tilde{f} \in L_2 \left( Q_T \right) \cap L_2 \left( \mathbb{R}^3 \right), \quad \nabla^2 \tilde{f} \in L_2 \left( Q_T \right) \cap L_2 \left( \mathbb{R}^3 \right) \]

and

\[ \max_{k} \| Q q_k \|_{L_2} \leq \text{const}, \quad \max_{k} \| Q f \|_{L_2} \leq \text{const}, \quad \max_{k} \| Q \tilde{f} \|_{L_2} \leq \text{const}, \quad \max_{k} \| Q \tilde{f} \|_{L_2} \leq \text{const}. \]

Then, there exists a unique generalized solution of (34), (35), (36) satisfying the following inequality:

\[ \max_{i} \sum_{i=0}^{3} \max_{x} |q_i| \leq \text{const} \]

where the value of \( \text{const} \) depends only on the conditions of the theorem.

Proof. It suffices to obtain uniform estimates of the maximum velocity components \( q_i \), which obviously follow from \( \max |q_i| \) because uniform estimates allow us to extend the local existence and uniqueness theorem over the interval in which they are valid. To estimate the velocity components, Lemma 22 can be used:

\[ v_i = q_i \left( \int_{0}^{t} \| q_i \|_{L_2(x')} \, d\tau + A_0 + 1 \right), \quad A_0 = \frac{4}{v^3 \left( CC_0 + 1 \right)^2}. \]

Using Lemmas (25)-(29) for

\[ v_i = q_i \left( \int_{0}^{t} \| q_i \|_{L_2(x')} \, d\tau + A_0 + 1 \right) \]

we can obtain \( \| A \|_{L_2} \leq \alpha < 1 \), where \( A \) is the amplitude of potential \( v_i \) and \( N(v_i) < 1 \). That is, discrete solutions are not significant in proving the theorem, so its assertion follows the conditions of Theorem 6, which defines uniform time estimations for the maximum values of the velocity components.

\[ \| \nabla v \|_{L_2(x')} + \int_{0}^{t} \int_{\mathbb{R}^3} |v| \, d\tau \, d\tau \leq \text{const} + \max |v_i| \left( \int_{0}^{t} \| \nabla v \|_{L_2(x')} \right) \left( \int_{0}^{t} \| \nabla^2 v \|_{L_2(x')} \right) \, d\tau. \]  

(57)

Theorem 6 asserts the global solvability and uniqueness of the Cauchy problem for the Navier-Stokes equations.
Theorem 7. Let
\[ q_0 \in W^2_z(R^3), \quad \nabla^2 \tilde{q}_0 \in L^2(R^3), \quad f \in L^2(Q_T), \quad \tilde{f} \in L^1(Q_T) \cap L^2(R^3) \]
\[
\lim_{t \to -\infty} \nabla q \|_{L^2(x^1)} = \infty.
\] (58)

Then, there exists \( i, j \) and \( x_0 \)
\[
\lim_{t \to -\infty} \psi_j(x_0, t) = \infty \quad \text{or} \quad \lim_{t \to -\infty} N(q_j) = \infty.
\] (59)

Proof. A proof of this lemma can be obtained using \( q_i = P_{a_i}q_i + P_{a_i}q_i \) and uniform estimates \( P_{a_i}q_i \).

Theorem 7 describes the loss of smoothness of classical solutions for the Navier-Stokes equations. Theorem 7 describes the time blow up of the classical solutions for the Navier-Stokes equations arises, and complements the results of Terence Tao [17].

4. Conclusion

New uniform global estimations of solutions of the Navier-Stokes equations indicate that the principle modeling of complex flows and related calculations can be based on the Fourier transform method.
