Abstract
This paper is introduced as a survey of the results on some generalization of Banach's fixed point, their approximations to the fixed point and error bounds, and also contains some new fixed point theorems and applications.

Keywords
Fixed Point Theorems, Error Bounds, Linear Algebraic Equations, Nonlinear Equation

Subject Areas: Functional Analysis, Numerical Mathematics

1. Introduction
An interesting generalization of the Banach contraction principle is given by Boyed and Wong [1] and non-archimedean version of the results in this subject has been recently studied by De Kimpe and Siddiqui [2].

The Fixed points have long been used in analysis to solve various kinds of partial differential equations, ordinary differential equations and integral equations [3]. Cauchy (1789-1857) did fundamental work on existence theorems in differential equations. Fixed point theorems of ordered Bananch spaces provide us exact or approximate solutions of boundary-value problems. For details, one can refer to Amann [4], Collatz [5] and Franklin [6].

Definition 1.1. Let $X$ be a set and $T: X \rightarrow X$ be a mapping. A fixed point of the mapping $T$ is a point $x \in X$ such that $Tx = x$. In other words, a fixed point of $T$ is a solution of the functional equation $Tx = x$.

Definition 1.2. Let $T$ be a mapping of a metric space $X$ into itself then $T$ is called a contraction mapping if there exists a constant $L$, $0 \leq L < 1$, such that $d(T(x), T(y)) \leq Ld(x, y)$ for all $x, y \in X$.

Theorem 1.3. [8] Every contraction mapping $T: X \rightarrow X$ defined on a complete metric space $X$ into itself
has a unique fixed point \( u \in X \). Moreover, if \( x_0 \) is any point in \( X \) and the sequence \( x_n \) is defined by
\[
x_i = T(x_0), x_2 = T(x_1), \ldots, x_n = T(x_{n-1}),
\]
Then \( \lim_{n \to \infty} x_n = u \) and
\[
d(x_n, u) \leq \frac{L^n}{(1-L)} d(x_1, x_0)
\]
and that \( L \) is as in Definition 1.2.

**Corollary 1.4.** [8] Let \( L(X, d) \) be a complete metric space and \( T: X \to X \) be a contraction on a closed ball \( B(x_0, r) = \{x : d(x, x_0) \leq r\} \). Moreover, assume that \( d(x_0, Tx_0) \leq (1-L)r \). Then the iterative sequence (1) converges to an \( u \in B \). This is a fixed point of \( T \) and is the only fixed point of \( T \) in \( B \).

### 2. Some Results on Fixed Point

In this section, we give some result on fixed point in complete metric space and its applications.

**Theorem 2.1.** If \( X \) is a complete metric space, and let \( T: X \to X \) be a map such that \( T^r \) is contraction for some integer \( r > 0 \). Then for every \( n \in \mathbb{N} \) and \( y \in X \)
\[
\lim_{n \to \infty} T^n(y) = u.
\]

**Proof:** Since \( T^r \), where \( r \) is a positive integer, is a contraction mapping by Theorem 1.3, there exists an unique fixed point \( u \) of \( T^r \) i.e. \( T^r(u) = u \). Now, let \( S = T^r \), therefore, \( S(u) = u \). This implies that
\[
S^2(u) = S(S(u)) = S(u) = u,
\]
\[
S^3(u) = S^2(S(u)) = S^2(u) = u,
\]
\[
S^4(u) = S^3(S(u)) = S^3(u) = \cdots = u,
\]
and so \( T(u) = T(S^r(u)) = S^r(T(u)) = S^r y \). Therefore for every \( n \geq 1 \) and \( y \in X \),
\[
d(S^n(y), u) = d(S^n(y), S^n(u)) \leq c d(S^{n-1}(y), S^{n-1}(u))
\]
\[
\leq c^2 d(S^{n-2}(y), S^{n-2}(u)) \leq \cdots \leq c^n d(y, u).
\]

It follows that
\[
\lim_{n \to \infty} d(S^n(y), u) = 0,
\]
since \( c^n \to 0 \). thus, \( \lim_{n \to \infty} S^n(y) = u \). \( \lim_{n \to \infty} T^n(y) = u \). □

**Theorem 2.2.** Let \( L(X, d) \) be a complete metric space and let \( T: X \to X \) and \( S: X \to X \) be two maps contraction. If for every \( x \in X \), chosen suitably. Then for every \( x \in X \),
\[
d(T^nx, S^ny) \leq \lambda \frac{1-L^n}{1-L}, \quad m = 1, 2, \ldots
\]
and that \( L \) is as in Definition 1.2.

**Proof:** The relation is true for \( m = 1 \). We use the principle of induction in order to prove this relation. Let it be true for all \( m \geq 1 \). Then,
\[
d(T^{m+1}x, S^{m+1}x) = d(TT^m(x), SS^m(x))
\]
\[
\leq d(TT^m(x), TS^n(x)) + d(TS^n(x), SS^m(x))
\]
\[
\leq Ld(T^m(x), S^n(x)) + \lambda \leq L\lambda \frac{1-L^n}{1-L} + \lambda
\]
\[
= L\lambda - L^{m+1} \lambda + \lambda - L\lambda = \lambda \frac{1 - L^{m+1}}{1 - L}
\]
Thus, the relation is true for \( m + 1 \). □
**Corollary 2.3.** Let $L(X,d)$ be a complete metric space and let $T:X \to X$ be a contraction on $X$. Moreover, the iteration sequence

$$x_1 = T(x_0), x_2 = T^2(x_0), \ldots, x_n = T^n(x_0)$$

with arbitrary $x_0 \in X$ converges to the unique fixed point $u$ of $T$. Error estimate is the following estimate:

$$d(x_n, u) \leq \frac{L^n}{1-L} d(x_0, x_1), \quad m = 1, 2, \ldots$$

**Proof:** The first statement is obvious by

$$d(x_n, x_m) \leq d(x_n, x_{m+1}) + d(x_{m+1}, x_{m+2}) + \cdots + d(x_{n-1}, x_n)$$

$$\leq (L^n + L^{n+1} + \cdots + L^{m-1}) d(x_0, x_1)$$

thus

$$d(x_n, x_m) \leq \frac{L^n}{1-L} d(x_0, x_1), \quad (n > m).$$

Now, inequality (3) follows from (4) by letting $n \to \infty$. We have $d(x_n, x_m) \leq \frac{L^n}{1-L} d(x_0, x_1)$. \hfill $\square$

**Corollary 2.4.** Let $L(X,d)$ be a complete metric space and $T:X \to X$ be a contraction on a closed ball $B(x_0, r) = \{ x : d(x, x_0) \leq r \}$. Moreover, assume that $d(x_0, Tx_0) \leq (1-L)r$. Then prior error estimate is the following estimate:

$$d(x_n, u) \leq L^n r.$$

**Proof:** By Corollary (2.3) the iteration sequence is converges to the unique fixed point $u$ of $T$, and

$$d(x_n, x_0) \leq \frac{L^n}{1-L} d(x_0, x_1),$$

since $x_i = Tx_0$ and $d(x_0, Tx_0) \leq (1-L)r$, we have

$$d(x_n, u) \leq \frac{L^n}{1-L} d(x_0, x_1) = \frac{L^n}{1-L} d(x_0, Tx_0)$$

$$\leq \frac{L^n}{1-L}(1-L)r = L^n r.$$

Therefore $d(x_n, u) \leq L^n r$. \hfill $\square$

### 3. Applications of Banach Contraction Principle on Complete Metric Space

In this section, we apply Theorem 1.3 to prove existence of the solutions a system of $n$ linear algebraic equations with $n$ unknowns, and we show that applied of Corollary 2.3 and 2.4 in numerical analysis.

**Application 3.1.** Suppose we want to find the solution of a system of $n$ linear algebraic equations with $n$ unknowns:

$$\begin{align*}
a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= b_1 \\
a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= b_2 \\
\vdots & \quad \vdots \\
a_{n1}x_1 + a_{n2}x_2 + \cdots + a_{nn}x_n &= b_n
\end{align*}$$

This system can be written as:
By assuming \( a_i = a_j + \delta_{ij} \), where

\[
\delta_{ij} = \begin{cases} 
0 & i \neq j \\
1 & i = j 
\end{cases}
\]

Equation (6) can be written in the following equivalent form.

\[
x_i = \sum_{j=1}^{n} a_{ij} x_j + b_i \quad i = 1, 2, 3, \ldots, n
\]

(7)

If \( x = (x_1, x_2, \ldots, x_n) \in R^n \) then Equation (7) can be written in the form \( T(x) = x \), where \( T : R^n \to R^n \) is defined by

\[
Tx = y \quad \text{where} \quad y = (y_1, y_2, \ldots, y_n)
\]

and

\[
y_i = \sum_{j=1}^{n} a_{ij} x_j + b_i \quad i = 1, 2, 3, \ldots, n
\]

Finding solutions of the system described by Equations (5) or (6) is thus equivalent to finding the fixed point of the operator equation, Equation (8). In order to find a unique solution of \( T \), i.e., a unique solution of Equation (8), we apply Theorem (1.3). In fact, we prove the following result. Equation (5) has a unique solution, if

\[
\sum_{j=1}^{n} |a_{ij}| = \sum_{j=1}^{n} |a_{ij} + \delta_{ij}| \leq L < 1, \quad i = 1, 2, 3, \ldots, n
\]

For \( x = (x_1, x_2, \ldots, x_n) \) and \( x' = (x'_1, x'_2, \ldots, x'_n) \), we have

\[
d(Tx, Tx') = d(y, y')
\]

where

\[
y = (y_1, y_2, \ldots, y_n) \in R^n
\]

\[
y = (y'_1, y'_2, \ldots, y'_n) \in R^n
\]

\[
y_i = \sum_{j=1}^{n} a_{ij} x_j + b_i
\]

\[
y'_i = \sum_{j=1}^{n} a_{ij} x'_j + b_i \quad i = 1, 2, 3, \ldots, n
\]

If \( y = (y_1, y_2, \ldots, y_n) \in R^n \), then \( d(y, y) = \sup_{i \leq n} |y_i| \). Therefore,

\[
d(Tx, Tx') = \sup_{i \leq n} |y_i - y'_i| = \sup_{i \leq n} \left| \sum_{j=1}^{n} a_{ij} x_j + b_i - \sum_{j=1}^{n} a_{ij} x'_j - b_i \right|
\]

\[
= \sup_{i \leq n} \left| \sum_{j=1}^{n} a_{ij} (x_j - x'_j) \right| \leq \sup_{i \leq n} \sum_{j=1}^{n} |a_{ij}| |x_j - x'_j|
\]

\[
\leq \sum_{i \leq n} |a_{ij}| \sum_{j=1}^{n} |x_j - x'_j| \leq L \sum_{i \leq n} |x_j - x'_j|
\]

Since \( d(x, x') = \sup_{i \leq n} |x_j - x'_j| \), we have \( d(Tx, Tx') \leq Ld(x, x') \), \( 0 \leq L < 1 \), i.e., \( T \) is a contraction mapping of the complete metric space \( R^n \) into itself. Hence, by Theorem 1.3, there exists a unique fixed point \( u \)}
of $T$ in $R^n$ i.e. $u$ is a unique solution of Equation (5). $\square$

**Theorem 3.2.** If $f(t)$ be a nonlinear integral equation as following:

$$f(t) = \int_{0}^{t} e^{-st} \cos(pf(t)) \, dv, \quad 0 \leq t \leq 1; \quad 0 < p < 1$$

Then it has a unique solution.

**Proof:** We apply the Theorem 1.3, we can prove that this equation has a unique continuous real-valued solution $f(t)$. Let $X = C[0,1]$, and the mapping $T: X \rightarrow X$ defined by $T(f) = f$ for $f \in X$, where $X$ is a complete metric space with $\sup d(x,y)$, is a contraction mapping:

$$\cos(pa) - \cos(pb) = p(b-a)\sin \alpha$$

where $\alpha$ lies between $pa$ and $pb$. Therefore, $|\cos(pa) - \cos(pb)| \leq p|b-a|$.

For functions $a(t)$ and $b(t)$; we get

$$|\cos pa(t) - \cos pb(t)| \leq \sup_{pa(t) \leq pb(t)} |a(t) - b(t)| = d(a,b)$$

For $f = Tf$ and $g = Tg$, we have

$$|Tf - Tg| = \int_{0}^{t} e^{-st} \left[ \cos(pf(v)) - \cos(pg(v)) \right] \, dv$$

$$\leq \int_{0}^{t} e^{-st} \left[ \cos(pf(v)) - \cos(pg(v)) \right] \, dv$$

$$\leq pd(f,g) \int_{0}^{t} e^{-st} \, dv \leq pd(f,g)$$

Taking sup over $0 \leq t \leq 1$, we get

$$\sup |Tf(t) - Tg(t)| \leq pd(f,g)$$

or

$$d(T(f),T(g)) \leq pd(f,g). \quad \square$$

**Theorem 3.3.** Let $x_0$ be an initial value and the iterative sequence $\{x_n\}$ as following:

$$x_n = g(x_{n-1}) \quad n = 1,2,\ldots$$

If $g$ is continuously differentiable on some interval $k = [x_0 - r, x_0 + r]$ and satisfies $|g'(x)| \leq L < 1$ on $k$ as well as

$$|g(x_0) - x_0| < (1-L)r.$$ (9)

Then $x = g(x)$ has a unique solution $u$ on $k$, the iterative sequence $\{x_n\}$ converges to that solution, and one has the error estimates

$$|x - x_n| < L^n r, \quad |x - x_n| < Lr.$$ (10)

**Proof:** Suppose that $d(x,g(x)) = |x-g(x)|$ for $x \in k$. By the mean-value theorem and the given condition, $g(x)$ is a contraction mapping of the complete metric space $k$ into itself. Hence, by Corollary 1.4 there exists a unique fixed point $u$ of $g$ in $k$, i.e. $u$ is a unique solution of $x = g(x)$. Also, the iteration sequence $\{x_n\}$ converges to $u$. Moreover, by $d(x,g(x)) = |x-g(x)|$ and Corollary 2.4 it has the prior error

$$|x - x_n| < L^n r,$$ and the posterior estimate

$$|x - x_n| < Lr. \quad \square$$
