ABSTRACT
Maize tassel-multiwalled carbon nanotube (MT-MWCNT) composite has been used as a matrix for physical adsorption of horseradish peroxidase (HRP) onto the surface of a glassy carbon electrode through electrostatic interactions. The HRP/MT-MWCNT biosensor was applied for the detection of Zn$^{2+}$ in aqueous solution. The biosensor designed was able to determine Zn$^{2+}$ in the range of 0.35 - 12 mg/L with a detection limit of 7.5 µg/L. The inhibition was found to be reversible and uncompetitive when data were modeled using the Dixon and Cornish-Bowden plots. The biosensor was found to have good repeatability, reproducibility and high selectivity. The developed biosensor can be used to detect other HRP inhibiting trace metal ions.

1. Introduction
Powerful analytical techniques, such as atomic absorption spectroscopy, isotope dilution inductively coupled plasma mass spectrometry, inductively coupled plasma optical emission spectrometry and voltammetric methods, are widely used and are commercially available for detecting heavy metals ions. These techniques exhibit high sensitivity, selectivity, reliability, and accuracy. On the other hand, they are very time-consuming for sample pretreatment and expensive, and they can be performed only by qualified and experienced technicians [1-3]. The heavy metals to be determined are non-degradable, cannot be detoxified biologically and can accumulate in the biosphere and transfer to the alimentary chain, thereby giving rise to potential serious health consequences for human beings, animals and plants [4]. The toxicity of heavy metal ions result mainly from their interaction with enzymes by binding to the sulphhydryl groups, leading to inhibition in metabolism and the function of numerous enzymes and hormones [5]. Of particular interest in this study is zinc metal ion. Zinc is a trace element that is essential for human health. When people absorb too little zinc they can experience a loss of appetite, decreased sense of taste and smell, slow wound healing and skin sores. Zinc shortages can even cause birth defects. On the other hand, although humans can handle large concentrations of zinc, too much zinc can still cause eminent health problems, such as stomach cramps, skin irritations, vomiting, nausea and anaemia. Very high levels of zinc can damage the pancreas and disturb the protein metabolism, and cause arteriosclerosis. Zinc contagion can lead to a flu-like condition known as metal fever and can be a danger to unborn and newborn children through blood or milk of their mothers when they have absorbed large concentrations of zinc. For these reasons, there is a considerable interest in the development of highly sensitive, selective, rapid and reliable analytical methods in their detection.

Enzyme based biosensors represent an alternative method to quickly detect trace metal ions through inhibition. They possess advantages such as minimum sample pretreatment, low cost and less time of analysis, and sufficient sensitivity and selectivity [6-8]. In inhibition-based enzyme biosensors, the concentration of heavy metal ions in an assayed sample is determined through either direct or indirect inhibition methods with lower detection
limits. The detection principle of the enzyme-based biosensors is based on the target analyte selectively inhibiting the activity of the immobilized enzyme resulting in a decrease in voltammetric signal. A decrease in enzyme activity below normal values can serve as a standard measure which is an indicator of possible heavy metal poisoning.

In this study, horseradish peroxidase (HRP) was immobilized onto maize tassel-multiwalled composite (MT-MWCNT) through adsorption to construct an inhibitor biosensor for the determination of Zn$^{2+}$ ions in aqueous solution. The measurement was performed with Zn$^{2+}$ inhibiting the catalytic activity of HRP enzyme to reduce H$_2$O$_2$. The decrease in the reduction current is expected to be proportional to the concentration of the Zn$^{2+}$ ion in solution. The mode of inhibition was investigated using the Dixon and Cornish-Bowden plots.

2. Experimental

2.1. Reagents and Apparatus

All reagents were of analytical grade and were used without further purification. Horseradish peroxidase (HRP, 250 U mg$^{-1}$), N,N-dimethylformamide (DMF), Nafion (5% ethanol solution), Multi-walled carbon nanotube (MWCNT), Zn(NO$_3$)$_2$ were purchased from Sigma-Aldrich (South Africa). Hydrogen peroxide (H$_2$O$_2$, 30% w/w) was obtained from Merck (South Africa) and solutions were freshly prepared before being used. Phosphate buffer solutions with various pH values were prepared by mixing standard stock solutions of 0.1 M Na$_2$HPO$_4$ and 0.1 M NaH$_2$PO$_4$ and adjusting the pH with 0.1 M H$_3$PO$_4$ or NaOH from Merck, South Africa. All solutions were prepared using Milli-Q water (resistivity >18 MΩcm$^{-1}$).

All electrochemical experiments were performed with a Bioanalytical Systems (USA) CV-50 W conventional three-electrode system. A three-electrode system was employed with an Ag/AgCl as the reference electrode, a platinum wire as the counter electrode, and the modified electrodes as the working electrodes. The phosphate buffer solution was kept in thoroughly anaerobic conditions by purging it with high-purity nitrogen for at least 15 min before and continuously during the experiments. FT-IR spectra of the free HRP, HRP/MT-MWCNT film and MT-MWCNT film were obtained using a Nicolet 380 FT-IR spectrometer (Thermo Scientific). After enzyme immobilization, the film was scraped gently from the electrode surface. The HRP/MT-MWCNT film, free HRP and MT-MWCNT film were analyzed directly using the diamond tip in the region 400 - 4000 cm$^{-1}$. To avoid interferences from CO$_2$ and water, IR chamber was flushed with N$_2$ gas and fresh background was recorded and utilized prior to recording spectra of sample. All measurements were carried out at room temperature (25°C ± 2°C).

2.2. Preparation of the Maize Tassel Powder

The maize tassel (MT) powder was prepared using a reported procedure [9]. Briefly, maize tassel was plucked off the woody parts of the maize plant, thoroughly washed with water and air-dried at room temperature. The material was then milled and fractionated to obtain particles of diameter range of 50 - 100 μm which were washed twice with 0.01 M Hydrochloric acid (HCl) in order to remove any impurities that might be on the powder. The acid-washed biomass was then washed twice with high purity water prior to electrode modification.

2.3. Fabrication of HRP Biosensor

The biosensor was prepared following the steps described in our previous work [8]. Briefly, prior to modification, the GC electrode (φ = 4 mm) was polished to a mirror finish by use of the BASi polishing kit with 1.0, 0.3 and 0.05 μm diamond slurry in sequence, rinsed thoroughly with ultra-pure water, then ultrasonically rinsed with ethanol and ultra-pure water for 10 min in sequence, in order to remove any adsorbed substances on the electrode surface. The cleaned GC electrode was dried in air. The composite was prepared by dispersing MT-MWCNT (4:1 w/w) with the aid of ultrasonic agitation for 1 h in 10 mL of N,N-dimethylformamide (DMF) to give a 0.1 mg mL$^{-1}$ yellow-black solution. A 10 μL drop of this dispersion was cast onto the surface of a GC electrode and after drying in air, 10 μL horseradish peroxidase (HRP) solution (10 mg mL$^{-1}$, dissolved in 0.1 mol L$^{-1}$ pH 7.0 phosphate buffer solution, PBS) and 0.5 μL of 0.3% Nafion to act as a binder was deposited on MT-MWCNT composite (see Figure 1).

2.4. Inhibition Studies

The determination on the decrease in the current obtained for the reduction of H$_2$O$_2$ by HRP using voltammetry was used as basis of evaluation. The process was carried out in a three step procedure. The biosensor response was first measured in 0.1 M PBS, (0.1 M KCl, pH 7.0) and 0.1 mM H$_2$O$_2$ to have steady-state current before inhibition (I$_0$). The electrode was then washed with the same buffer and incubated in solution containing known concentrations of Zn$^{2+}$ (0.35 - 6.0 mg L$^{-1}$). After incubating for 20 min, the modified electrode response was measured and this corresponded to steady-state current after inhibition (I). The percentage of HRP inhibition (%Inhibition) and residual enzyme activity (%REA$\text{H}_{\text{R}}$) were calculated using Equations (1) and (2) [10]:

\[
\%\text{Inhibition}(\%) = \frac{(I - I_{0})}{I_{0}} \times 100
\]

3. Results and Discussion

3.1. Physical Characterization

The interaction between HRP and MT-MWCNT was evaluated with the FT-IR spectra of HRP, HRP/MT-MWCNT film and MT-MWCNT composite film. The shapes and positions of the amide I (1700 - 1600 cm\(^{-1}\)) and amide II (1620 - 1500 cm\(^{-1}\)) infrared absorbance bands of proteins provide detailed information on the secondary structure of polypeptide chain of the proteins [11,12]. Figure 2 (curve a) shows the FTIR spectrum of free HRP. The amide I band of HRP, which is caused by \(\text{C=O}\) stretching vibrations of peptide linkages, appeared at 1641 cm\(^{-1}\). The signal at 1516 cm\(^{-1}\) indicates the characteristic of amide II, which may have originated from a combination of N-H in plane bending and C-N stretching vibrations of the peptide groups. In Figure 2 (curve b) the FTIR spectrum of HRP immobilized on the surface of MT-MWCNT is shown. It can be seen in Figure 2 (curve b) that the amide I and II bands in FTIR spectrum exhibited similar shapes to that of free HRP in the FT-IR spectrum (curve a) except that the bands only shifted slightly to 1636 and 1514 cm\(^{-1}\), respectively. The FTIR spectrum of MT-MWCNT did not show observable peaks in the range of amides II (curve a). The FTIR results indicated that the structure of HRP remained almost unchanged in MT-MWCNT composite.

\[
\text{% Residual enzyme activity (REA%)} = \frac{(I_T)}{I_i} \times 100
\]

3.2. Biosensor Characterization

The enzymatically reduction of \(\text{H}_2\text{O}_2\) was evaluated by using the fabricated HRP biosensor by cyclic voltammetry in 0.1 M PBS at pH 7.0. At these experimental conditions, a cathodic peak around \(-320\) mV versus Ag/AgCl was obtained. Figure 3 shows the cyclic voltammograms of the biosensor in the absence (ab) and presence of \(\text{H}_2\text{O}_2\) (0.01 - 0.5 mM) (b to f) in PBS (pH 7.0) at the scan rate of 100 mV s\(^{-1}\). An increase in cathodic peak current was observed with increase in substrate concentration.

3.3. Inhibition Studies

Typical percentage inhibition-concentration and percentage residual activity-concentration plots of the HRP/MT-MWCNT biosensor under the optimized experimental conditions for Zn\(^{2+}\) are displayed in Figure 4.
As shown in Figure 4, this type of inhibition effect exhibited dose-dependent behavior. The percentage inhibition increased with increase in concentrations of Zn$^{2+}$ ions. As can be seen in Figure 4, 25.4.0% of the activity of HRP was inhibited by 5 mg L$^{-1}$ for Zn$^{2+}$. Zn$^{2+}$ had a linear range up to 12.0 mg L$^{-1}$, and the detection limit was 7.5 µg L$^{-1}$. The results obtained for this biosensor were comparable to those reported in literature. Using glucose oxidase immobilized in poly(neutral red) a linear range up to 2.5 mg L$^{-1}$ and a detection limit of 9 µg L$^{-1}$ was reported for Zn$^{2+}$ [13]. In another study, Zn$^{2+}$ was determined by a conductometric nitrate reductase biosensor and gave a linearity of 40 µmol L$^{-1}$ and a detection limit of 0.5 µmol L$^{-1}$ [14]. The residual enzyme activity decreased with increase in heavy metal ion concentration.

3.4. Investigation on the Type of Inhibition

The mode of enzymatic reversible inhibition is variable from one inhibitor to another, and may be competitive, non-competitive, and uncompetitive or mixed inhibition [15,16]. In this study, the type of inhibition shown by Zn$^{2+}$ over immobilized HRP was studied using increasing concentrations of the trace metal and of the substrate, H$_2$O$_2$. Moreover, data modelling using Dixon plot (representation of the inverse of the enzyme activity vs. inhibitor concentration) and Cornish-Bowden plot (the ratio of substrate concentration and enzyme activity vs. inhibitor concentration) was utilized to verify the inhibition mode [17,18]. During inhibition, it should be noted that the different types of inhibition can be characterized by analyzing these two plots together. The Dixon plot by itself cannot clearly distinguish between competitive and mixed inhibition and on the other hand, the Cornish-Bowden plot cannot always distinguish between mixed and uncompetitive inhibition. In this study, the type of inhibition shown by Zn$^{2+}$ was studied using three different concentrations of H$_2$O$_2$ (0.05, 0.2, and 1.0 mM). Representative Dixon and Cornish-Bowden plots are shown in Figures 5A and B for Zn$^{2+}$.

The pattern of inhibition shows that the Dixon plot lines are parallel (Figure 5A) hence the inhibition constant could not be determined. In the Cornish-Bowden plot, the lines intersect above the second quadrant above the x-axis, giving a value of $K'_i$ (1.2 mg L$^{-1}$) (see Figure 5B) and showing that the inhibition is uncompetitive. In uncompetitive inhibition, binding occurs only to ES...
complexes at locations other than the catalytic site (see Figure 6). The substrate binding modifies enzyme structure, making inhibitor-binding site available [15,16,19]. In the Figure 6, E represents the HRP enzyme; S represents $\text{H}_2\text{O}_2$; ES represents Compound I containing an oxylferryl centre and porphyrin cation radical; EIS represents HRP-$\text{Zn}^{2+}$-$\text{H}_2\text{O}_2$ complex; I represents the $\text{Zn}^{2+}$ and P represents $\text{H}_2\text{O}$.

3.5. Selectivity of HRP/MT-MWCNT Biosensor

Selectivity is an important parameter in the performance of an HRP/MT-MWCNT inhibition based biosensor. The addition of the following interferents; cations such as $\text{Ca}^{2+}$, $\text{Mg}^{2+}$, $\text{Na}^+$, $\text{K}^+$ and anions: $\text{F}^-$, $\text{CN}^-$, $\text{SO}_4^{2-}$, $\text{CO}_3^{2-}$ were studied by the mixed method, using the ratio of 1:2 for analyte and interferents, respectively. From the results in Table 1, the cations and anions do not cause much decrease in biosensor response, except $\text{CN}^-$ anions as also reported [20].

![Figure 6. Mechanism for reversible, uncompetitive inhibition.](image)

3.6. Application

To demonstrate the feasibility of the fabricated enzyme inhibition biosensor for possible environmental applications, preliminary application of the biosensor was examined by determination of $\text{Zn}^{2+}$, in tap water by standard addition method. The results are given in Table 2. The recoveries were in the range of 98.0% - 103.0%, which indicated the efficacy of the biosensor for practical analysis.

The validation of the HRP/MT-MWCNT biosensor measurements against the ICP-OES technique verified the suitability of biosensor for rapid analysis of trace elements in natural water standard reference material\(^\text{®}\), 1640a. The concentration of $\text{Zn}^{2+}$ (3.98 µg L\(^{-1}\)) in the natural water standard reference material\(^\text{®}\) from National Institute of Standard and technology (NIST) were calculated from the calibration curves. The obtained results after analysis for the trace metal presented in Table 3, corroborated well with those obtained by ICP-OES, with relative error values lower than 10%.

The allowed maximum contaminant levels (MCLs) by USEPA [21] in drinking water is 1 300 µg L\(^{-1}\) for $\text{Zn}^{2+}$. The World Health Organization [22] on the other hand has given the guideline values for $\text{Zn}^{2+}$, in drinking water as 2 000 µg L\(^{-1}\). Based on this, it can be suggested that the HRP/MT-MWCNT biosensor could be used as a management tool for determining the quality of water for the presence of $\text{Zn}^{2+}$ ions.

3.7. Stability, Repeatability and Reproducibility

The stability of the biosensor was first examined in the presence of 0.1 mM $\text{H}_2\text{O}_2$ concentration in 0.1 M PBS (pH 7.0). For the same metal concentration, it was observed that after 10 successive series of measurements, the biosensor lost about 30% of the initial sensitivity. In studying the long-term stability, the HRP/MT-MWCNT biosensor was stored in 0.1 M PBS at 4 °C for 18 days and the biosensor response was tested on different days after incubation in the inhibitor. The biosensor did not

show a bigger decrease of its initial response for 0.1 mM H$_2$O$_2$ after incubation in standard Zn$^{2+}$ ion solution for the different days studied. The repeatability of the HRP/MT-MWCNT biosensor was investigated for fixed Zn$^{2+}$ ion concentrations. Relative standard deviations (RSD) of 5.3% were obtained for Zn$^{2+}$. Five modified biosensors were made independently and were investigated for the determination of the same concentrations of Cu$^{2+}$. The modified biosensors showed a relative standard deviation (RSD) of Zn$^{2+}$ (4.8%).

4. Conclusion

The use of an HRP/MT-MWCNT biosensor for the determination of Zn$^{2+}$ ions through inhibition studies has been demonstrated. It was deduced that HRP was inhibited by Zn$^{2+}$ ion. The highest inhibition result obtained for the HRP/MT-MWCNT biosensor was 25.4%. The metal ion was measured with a detection limit of 7.5 µg L$^{-1}$. By modelling the data and using the Cornish-Bowden together with Dixon plots, the inhibition was determined to be reversible and uncompetitive. The proposed biosensor does not require any complicated immobilization procedure for the construction and has been shown to detect low concentration in samples.
