Abstract

The spider family Linyphiidae comprises 104 species in Turkey that of them eight species are known from the caves, we recently started to conduct intensive taxonomic and faunistic studies on this family. The genus *Troglohyphantes* was described in 1882 by Joseph as a cave spider from Carniola in western Slovenia. Members of this genus inhabited cave environment, neighbouring habitat and some species of them are true troglobites. A new species of *Troglohyphantes* Joseph 1881 is described from Turkey. Differences between the new species and related species are discussed. *Troglohyphantes turcicus* sp. n. (Araneae: Linyphiidae) is described from Buzluk cave in Turkey. Drawing of characteristic features, the male palpal organs and the female genitalia are presented. Key to the species of *polyophthalmus* group is given including in *T. turcicus* sp. n.

Keywords

Linyphiidae; *Troglohyphantes*; New Species; Cave Spider; Turkey

1. Introduction

Cave dwelling spiders, as zoogeographic agents, are important for biospeleology [1]. The first study on cave dwelling spiders fauna of Turkey belongs to the French biospeleologist Fage [2], who revised cave dwelling spiders and described *Palliduphantes byzantinus* (Linyphiidae) as a new species dwelling in Yarımburgaz cave in İstanbul.

The spider family Linyphiidae consists of 104 species in Turkey [3] of these species, eight species are known from the caves, our study teams started detailed taxonomic and faunistic studies on this family [4]-[6].

*Note: This study was presented as a poster at the 27th European Congress of Arachnology.*

Genus *Troglohyphantes* was created in 1882 by Joseph as a cave spider from Carniola in western Slovenia. The members of this genus inhabited cave environment and neighbouring habitat and some species of them are true troglobites [7] [8]. Although this genus is represented by 129 species in Palearctic region [9], there are only three species known from Turkey, *Troglohyphantes gladius* Wunderlich, 1995, *Troglohyphantes pisidicus* Brignoli, 1971, *Troglohyphantes karolianus* Topçu, Türkeş & Seyyar, 2008 [6] [10] [11]. In this study, we described a new species from Turkey.

2. Materials and Methods

The specimen was collected by hand from Buzluk cave in Bilecik province and preserved in 90% ethanol. All drawing were made by using SZX-16 Olympus stereomicroscope with a camera lucida, photographs of the distinguishing features were take by means of Olympus DP-25 stereocamera. All measurements are in millimetres and were taken with a millimetric ocular lens.

3. Results

*Troglohyphantes turcicus* sp. n.

**Material:** ♂ (NUAM), Turkey: Bilecik province, Camiliyayla village, Başhöyük, Buzluk cave, 39˚48’N, 29˚46’E, 1470 m., 13.IX.2011, (leg. A. Topçu & O. Seyyar), 1 ♂ holotype, 3 ♀ paratype (Figures 1-4).

**Diagnosis:** *Troglohyphantes turcicus* sp. n. belongs to the *polyophthalmus* group (Fage’s group IV) (Deeleman-Reinhold, 1978) which has proximo-mesal part of cymbium consists of an upper and a lower protrusion,
apophysis or ridge, separated by a depression. Paracymbium with pocket (Figure 5). Radix with a distinct triangular sclerite on the ventral border, surface rough with hairs or papillae. Chelicera, including eliminating a large tooth, having three teeth (Figure 6).

Embolus with a dorsal bulge, bearing an apophysis, tip claw-like in most species. External branch of lamella clearly longer than internal branch, usually separated by an unscleroionzited zone (Figure 7, Figure 8). Epigyne with a well developed scape, the length and wide of median plaque almost equal, not much wider than long on longer than wide, lateral plates with posterior lobes. Fertilization ducts not sclerotized (Figure 9, Figure 10).

*Troglohyphantes turcicus* sp. n. similar to *gamsi* and *kordunlikanus*, but upper apophysis of the proximo-mesal and median part of cymbium protrusion (in lateral and dorsal aspect). Tip of embolus not claw, proximal of paracymbium indent to cymbium at the upper and middle part. Median apophysis more slope. The median part of epigyne exactly circle-shape and quite near to scape which part bent upward. In the vulvae, spermatecha bent to reverse of clock.

**Etymology:** The new species is named in honour of the country, Turkey.

**Description:** Holotype ♂, total length 3.00; cephalothorax 1.00 length, 1.20 wide, pale yellow, chelicera 1.10 length, 0.30 wide, yellow; sternum 0.85 length, 0.75 wide yellowish green, mandibula 0.45 length, 0.25 wide; opisthosoma 1.60 length, 1.10 wide pale brown, legs yellow.

Paratype ♀, total length 3.50; cephalothorax 1.50 length, 1.25 wide, pale yellow, chelicera 1.20 length, 0.35 wide, yellow; sternum 0.90 length, 0.75 wide yellowish green, mandibula 0.30 length, 0.25 wide; opisthosoma 2.25 length, 1.10 wide brown with median more light, legs yellow.

Spination of male legs; femur (3d, 1rl/4d, 1rl/2d, 2rl/3d); tibia (?/2rl, 7v/1d, 1rl, 5v/2d, 1rl, 5v); metatarsus (?/0/1d/1d/1rl).

Leg measurements of *Troglohyphantes turcicus* sp. n. is given (♂ and ♀) in **Table 1**.
