Abstract

Backgrounds: The treatment of choice has been drainage and definitive surgical treatment after an interval for acute pilonidal sinus abscess till now. Because of the high incidence of chronic pilonidal sinus disease following drainage and aiming the cure in one step, synchronous treatment choices to drainage have been attempted recently. We analyzed retrospectively 20 patients with pilonidal sinus abscess on whom we carried out drainage + marsupialization as single step treatment. Methods: Drainage + synchronous marsupialization results of 20 patients (17 male, 3 female) between 20 to 37 years of age (mean 28) were analyzed retrospectively on the parameters of operation time, recovery period, time to work-return and recurrence ratios.

Results: Operation times were between 15 to 25 minutes. Mean recovery period was 45 days (30-50 days), the mean period from operation to work-return was 24 (22-30) days. There were full recovery in 18 patients (90%) and recurrence in 2 patients (10%). Silver nitrate ablation treatment achieved cure in recurrence.

Conclusion: Drainage + Marsupialization is an applicable and successful combined choice in the treatment of Pilonidal sinus abscess.

Keywords: Pilonidal Sinus Abscess, Drainage, Marsupialization, Definitive Treatment, Combined Treatment

1. Introduction

Pilonidal sinus disease (PSD) is an acquired disease in especially young men with continuous oozing at the intergluteal sulcus [1]. The risk factors increasing PSD incidence are white race, young age, familial tendency, excessive sweating, long sitting periods, sedative life style, bad body sanitation, fatness, male gender and trauma to the coccyx region [2].

In spite of proposed different treatment modalities, there is no standardized treatment due to high recurrence ratio.

Pilonidal sinus abscess (PSA) (Figure 1) is seen as the first finding in half of the patients [3]. PSA may cause widening of lesion, increasing of sinus number and sepsis [1,2]. It may be fatal if remains untreated. Various complications like Septic arthritis, osteomyelitis, DIC, and toxic shock syndrome were reported [2,4,5,6]. The treatment of PSA has been simple drainage and definitive surgery after healing of abscess [7]. Because the recurrence is high following simple drainage, definitive surgery is necessary for total cure [8]. Today, alternative approaches that combine drainage and definitive surgery in one step get popularity. We reported 20 patients with PSA on whom we performed definitive surgery at the same time with drainage.

2. Methods

20 patients (17 (85%) male and 3 (15%) female) between 20 to 37 years of age (median 28) who came to our outpatient clinics with acute pilonidal sinus abscess (PSA) and operated between 2007 and 2009 were analyzed retrospectively.

All patients were treated with skin excision, curettage and in traflexion operation under spinal anesthesia. Metronidazole 0.5 mg IV and gentamicin 80 mg IV were given to the pts 30 minutes before operation for infection treatment. Gluteal skin stretched to both sides with plaster traction and the area was shaved. Abscess was drained...
ined at midline where it gave fluctuation and the skin around the area was removed by a vertical rhomboid excision paralleling the intergluteal sulcus (Figure 2). The abscess pouch was washed out with physiologic saline and 10% povidone iodine solutions. The wall of cavity was curetted and chronic granulation tissue was excised (Figure 3). Healthy skin was fixed to the sacral fascia with 2/0 polypropylene single stitch at superior, inferior and both lateral sides (marsupialization) (Figure 4). The mean operation time was between 15 to 25 minutes. Pts were given p.o ampicillin 375 mg three times a day for 5 days and discharged at post operative 2nd day. Serum physiologic dressing of the wound was made on every 2 days for first 10 post operative days and on every 3 day-interval after then until to total wound healing occurred. Pts were advised to take shower before every dressing. Stitches were removed on 15th day and periodical controls were made at 1st, 2nd, 3rd, 6th and 12th months (Figure 5).

3. Findings

Abscess pouch was running toward the right gluteal region in 13 (65%), to the left in 5 (25%) and to the superior in 2 (2%) of pts. Mean recovery period was 45 days (between 30 to 50 days); the mean work-return period was 24 days (22-30). 18 (90%) of pts showed total recovery though 2 pts (10%) developed chronic pilonidal sinus disease on midline. These 2 pts were treated with silver nitrate 20% solution ablation and recovered well. There was no recurrence in follow up period.
4. Results and Discussion

Mainstay of the treatment is drainage for PSA. Simple drainage and definitive surgery after an interval period has been accepted treatment. But, many of the patients, treated with simple drainage, develop chronic PDS until definitive surgery and many delay in definitive surgery may result in expansion of diseased area and development of new tracts, therefore, widening the operative field. To decrease chronic PSD development risk, drainage and combined definitive surgery concept was proposed. Drainage + m arcupitization was performed by Licheri on 43 patients with a cute abscess and succeeded in 81.3% of them. In his study, 4.7% of the pts developed chronic fistulas and 1.46% developed recurrence. 95% of the pts got totally recovered within 6 to 10 weeks [9]. Our pts number was half of that series, but still, operation time were similar. Our recurrance ratio was twice.

Midline skin excision provided easier drainage, cavity excision and closure of chronic granulation tissue.

Disadvantages of the method were long recovery and work-return periods.

Another method reported as successful was drainage + primary closure with 82% total recovery and 18% recurrence [10]. Drainage + l aying open was another recommended method [11].

Midline location of the sinus openings mostly in chronic and recurred PSD suggest that focus of the disease is midline. Thus, two studies which closed wound off-midline showed that t his type of closure improved wound healing [12,13].

5. Conclusions

PSA needs definitive treatment after drain age so that it should not become chronic disease. Drainage and combined definitive surgery (skin excision curettage and intraflexion operation) as a single step is a good alternative method in its treatment. This treatment provides the patient to be cured in one step surgery and excludes the complications of delay in definitive surgery, like risk of getting chronic disease and forming more sinus tracts. The results are promising with lower recurrence rate and small and good scar formation and future studies on more patients will show its efficiency.
