Abstract

We address the $T_c(s)$ and multiple gaps of La$_2$CuO$_4$ (LCO) via generalized BCS equations incorporating chemical potential. Appealing to the structure of the unit cell of LCO, which comprises sublattices with LaO and OLa layers and brings into play two Debye temperatures, the concept of itinerancy of electrons, and an insight provided by Tacon et al.’s recent experimental work concerned with YBa$_2$Cu$_3$O$_{6.6}$ which reveals that very large electron-phonon coupling can occur in a very narrow region of phonon wavelengths, we are enabled to account for all values of its gap-to-$T_c$ ratio ($2\Delta_0/k_BT_c$), i.e., 4.3, 7.1, $\approx$ 8 and 9.3, which were reported by Bednorz and Müller in their Nobel lecture. Our study predicts carrier concentrations corresponding to these gap values to lie in the range $1.3 \times 10^{21}$ - $5.6 \times 10^{21}$ cm$^{-3}$, and values of 0.27 - 0.29 and 1.12 for the gap-to-$T_c$ ratios of the smaller gaps.

Generalized BCS Equations, Chemical Potential, Two-Phonon Exchange Mechanism, Structure of the Unit Cell of LCO, Gap-to-$T_c$ Ratio, Effective Mass of Electrons, Number Densities of Charge Carriers

1. Introduction

It is well known that La$_2$CuO$_4$ (LCO) is an insulator. It becomes superconducting when suitably doped,

(La₀.₉₂₅Sr₀.₀₇₅)₂CuO₄ being an example which has a \( T_c \approx 38 \text{ K} \). Discovered by Bednorz and Müller [1], it occupies a unique position among all the high-temperature superconductors (HTSCs) that have been discovered so far for the following reasons:

1) Being the first SC to transcend the BCS barrier of \( T_c \approx 23 \text{ K} \), it heralded the era of high-\( T_c \) superconductivity and led to the discovery of YBCO and the Tl-, Bi- and Hg-based SCs—each of them being characterized by a \( T_c \) higher than even the liquefaction temperature of nitrogen. This of course is well known.

2) Unlike all the other HTSCs mentioned above, LCO contains predominantly only one species of ions that can give rise to pairing: La (strictly speaking, La₀.₉₂₅Sr₀.₀₇₅), which implies that pairing in it is governed by only one interaction parameter. This \textit{prima facie} poses a problem because application of the generalized BCS equations [2] (GBCSEs) to an SC with a \( T_c \) exceeding 23 K and possessing two gaps \( \Delta_{1} \) and \( \Delta_{2} > \Delta_{1} \) requires two-phonon exchange mechanism (TPEM) for pairing [3]; by this we mean that phonons are exchanged with two distinct sub-lattice structures. For all the other HTSCs mentioned above, this brings into play two interaction parameters because their sub-lattices contain predominantly two distinct species of ions that can cause electron-phonon interaction to take place, e.g., Y and Ba ions [4] in YBa₂Cu₃O₇ and any two [3] of the Tl, Ba, and Ca ions in Tl₂Ba₂CaCuO₆. This is also the case for the Bi-based [3] and iron-pnictide HTSCs [5].

3) When the problem mentioned above is addressed—by appealing to the structure of LCO as will be seen below—we find that the input of its \( T_c \) alone yields an interaction parameter that enables one to calculate both its gaps. This is in contrast with all the other HTSCs for which the input of two parameters from the set \( \{ T_c, \Delta_1, \Delta_2 \} \) is required to calculate the third.

The work reported here is motivated by the need to:

a) Bring the understanding of LCO in the framework of GBCSEs at par with that of all the other HTSCs noted above. This is done in the next section where for any \( T_c \) in the range 37 - 40 K, it is shown, in accord with experiment, that \( \frac{2\Delta_B}{k_B T_c} = 4.3 \), where \( k_B \) is the Boltzmann constant, and

b) Explain experimental values for the gap-to-\( T_c \) ratio other than 4.3, \( \approx 8 \) and 9.3, attention to which was drawn by Bednorz and Müller [6] in their Nobel lecture. The study of these multiple gap-values is taken up in Section 3 by following an approach that incorporates the chemical potential \( \mu \) into the equations for the \( \Delta \) and \( T_c \) of the SC. Such an approach for LCO is based on 1) equations given in two recent papers, one [7] of which sheds light on the BCS-BES crossover physics without appeal to scattering length theory, while the other [8] suggests the possibility of solving a long-standing puzzle posed by \( \text{SrTiO}_3 \) and 2) an idea inspired by another recent paper [9] where it has been pointed out that a very large electron-phonon coupling occurs in a very narrow region of phonon wavelengths for an HTSC.

The final section is devoted to a discussion of our findings.

2. LCO Addressed via GBCSEs

2.1. Debye Temperatures of La Ions in LCO

As noted [3]-[5] for all the HTSCs dealt with so far, the first step in their study via GBCSEs is to fix the Debye temperatures of the ions that may be causing pairing. This is done by applying the following equations to each of the sub-lattices of the HTSC comprising layers designated as \( A_xB_{1-x} \):

\[
\theta_D(A_xB_{1-x}) = x\theta_D(A) + (1-x)\theta_D(B)
\]

where \( \theta_D(A_xB_{1-x}) \) is the Debye temperature of the HTSC, and \( m_A, m_B \) is the atomic mass number of \( A(B) \). While Equation (1) has been used routinely for binary SCs, Equation (2) has been derived [2] by assuming that the constituents of any sub-lattice simulate the oscillations of a weakly coupled double pendulum. That the constituents of an anisotropic material \textit{must} have different \( \theta_D \)s because their masses are different is an idea that dates back to Born and Karmann [10].

The observation that \( \theta_D(A) \) and \( \theta_D(B) \) of an HTSC calculated via the above equations depend on the relative positions of \( A \) and \( B \) in the double pendulum suggests that the structure of the unit cell of the SC should be examined. On doing so we find that it is characterized by layers [11] of LaO, OLα, and CuO₂. This implies that
if La is the lower of the two bobs of the double pendulum in the layers that comprise one of the sub-lattices, it is the upper bob in the layers of the other sub-lattice. This feature brings into play two Debye temperatures, in the application of TPEM to LCO as for any of the other HTSCs, but only one interaction parameter because it is the same species of ions in both the sub-lattices that causes pairing.

Applying Equations (1) and (2) to the sub-lattice of LCO comprising OLa layers in which La is the lower of the two bobs, we find that [12] $\theta_D^D(OLA) = 370$ K leads to $370$ K and $635.2$ K which we do not require, $(3)$

$\theta_D(O) = \frac{m_{La}}{138.91} = 15.999$ have been used. The results for the sub-lattice comprising LaO layers are:

$\theta_D(O) = 431.1$ K and $\theta_D(O) = 308.9$ K.

2.2. Dealing with LCO with the Input of Its $T_c$

For the reason given above, GBCSE for $T_c$ of LCO in the two sub-lattice (two-phonon) scenario, obtained by putting $\lambda = \lambda_1 = \lambda_2$ in Equation (4) of [5], is:

$$1 = \lambda \int_0^{\theta_D(O)} dx \frac{\tanh(x)}{x} + \lambda \int_0^{\theta_D(O)} dx \frac{\tanh(x)}{x}$$

(5)

Note that the equivalent of Equation (5) for YBCO, for example, had two different interaction parameters: $\lambda_r$ and $\lambda_{ab}$. To determine these, the input of $T_c$ and either $\Delta_1$ or $\Delta_2$—together with the corresponding $\theta_D$s—was required. One could then calculate the remaining parameter of the set \{\$\Delta_1, \Delta_2\$\}. Since LCO is characterized by only one interaction parameter, it can be fixed via Equation (5) with the input of $T_c$ alone; we are then enabled to calculate both $\Delta_1$ and $\Delta_2$.

In writing Equation (5) we have dropped the superscripts of the two $\theta$s in the original equation. Solution of this equation with the input of $T_c = 38$, $\theta_D = 104.8$ K from Equation (3) and $\theta_D = 431.1$ K from Equation (4) yields

$$\lambda = 0.26818.$$ (6)

This leads to two values for the smaller gap and one for the larger gap via the following equations (Equations (3) and (5) of [5])

$$1 = \lambda \ln \left(1 + \frac{2k_B\theta_D}{W_1(0)}\right)$$

(7)

$$1 = \lambda \ln \left(1 + \frac{2k_B\theta_D}{W_2(0)}\right) + \lambda \ln \left(1 + \frac{2k_B\theta_D}{W_2(0)}\right) + \lambda \ln \left(1 + \frac{2k_B\theta_D}{W_2(0)}\right).$$

(8)

In these equations $W_1(0)$ is to be identified with the smaller gap $\Delta_{1,0}$ at $T = 0$ and $W_2(0)$ with the larger gap $\Delta_{2,0}$ at $T = 0$; two values of the former are obtained because $\theta_D$ in Equation (7) can be either 104.8 or 431.1 K. Our results then are:

$$2\Delta_{2,0}/k_BT_c = 4.27, \quad 2\Delta_{1,0}/k_BT_c = 0.27, \quad 1.12.$$ (9)

Because $T_c$ values of LCO reported in the literature vary from 36 - 40 K, we have given in Table 1 not only the results of the above calculations for $T_c = 38$ K, but also for four other values.

2.3. Results with a Different Value of Debye Temperature

It was mentioned above that in giving an account of the properties of LCO, Bednorz and Müller in their Nobel lecture [6] had noted that besides 4.3 for the ratio $2\Delta_{1,0}/k_BT_c$, the following values have also been reported: 7.1, 8 and 9.3. While our result for this ratio is in agreement with the value 4.3 for any $T_c$ between 37 and 40 K, the problem of explaining the larger values remains. We note in this connection that the value of $\theta_D$ (LCO)
Table 1. Values of the interaction parameter $\lambda$ of superconducting La$_2$CuO$_4$ obtained via Equation (5), and the associated gap-to-$T_c$ ratios for different values of $T_c$ obtained via Equations (8) and (7), respectively.

| $T_c$ (K) | $\lambda$ | $|W_{20}|$ (meV) | $|W_{\theta}(\theta)|$ (meV) | $2|W_{\theta}(\theta)|/k_B T_c$ | $|W_{20}|/k_B T_c$ | $2|W_{\theta}(\theta)|/k_B T_c$ | $|W_{20}|/k_B T_c$ |
|-----------|-----------|-----------------|-----------------|------------------|------------------|------------------|------------------|
| 36        | 0.26103   | 6.573           | 4.24            | 0.400            | 0.26             | 1.647            | 1.06             |

| 39        | 0.27173   | 7.207           | 4.29            | 0.467            | 0.28             | 1.922            | 1.14             |
| 40        | 0.27527   | 7.420           | 4.31            | 0.491            | 0.28             | 2.018            | 1.17             |

employed in our study is 370 K, whereas values both smaller (360 K [12]) and larger (385 K [13]) have also been reported in the literature. It therefore seems pertinent to investigate the extent to which the gap-to-$T_c$ ratio changes if one were to adopt the largest of these values, i.e., 385 K. We have carried out this exercise with the following results:

$$\theta_D (\text{La, OLa sub-lattice}) = 109.1 \text{ K, } \theta_D (\text{La, LaO sub-lattice}) = 448.5 \text{ K}$$

$$T_c = 36 \text{ K} : \lambda = 0.25596, \quad 2|\Delta_{20}|/k_B T_c = 4.21; \quad T_c = 40 \text{ K} : \lambda = 0.26973, \quad 2|\Delta_{20}|/k_B T_c = 4.28.$$  \hspace{1cm} (10)

From these results we conclude that all the different observed values of $2\Delta_{20}/k_B T_c$ of LCO cannot be explained on the basis of variation in the Debye temperatures of its different samples.

This study of LCO in the framework of Equations (5) and (8) parallels earlier studies [3]-[5] of various HTSCs in the same framework. Since at the end of it certain observed values of the gap-to-$T_c$ ratio remain unaccounted for, we are led to enlarge the framework employed by incorporating $\mu$ in the GBCSEs for $\Delta$ and $c_T$. This is the task taken up in the next section.

3. LCO Addressed via $\mu$-Incorporated GBCSEs

3.1. $\mu$-Incorporated GBCSEs in the One-Phonon Exchange Mechanism (OPEM) Scenario for a 1-Component SC

It was remarked in [6] that the existence of CPs in LCO is an established experimental fact and that while more than one interaction for pairing may be operative, the phonon mechanism cannot be ruled out. Also reported in this paper is the value of the carrier density in one sample of LCO as being of the order of $10^{21}$/cm$^3$, which is a parameter that is related to its Fermi energy. We now draw attention to the fact that Fermi energies of HTSCs have of late been attracting considerable interest, partly because their low values are believed [14] to be the cause of high-$T_c$s and partly because they shed light on the gap-structures of HTSCs. In the context of LCO it seems significant that, on the basis of a thorough theoretical investigation, Jarlborg and Bianconi [15] have recently reported three values for its Fermi energy: 60, 150, and 240 meV. We now recall that both the usual BCS equations and GBCSEs, Equations (5) and (8) above, are derived by assuming

$$E_s (\text{or } \mu) \gg k_B \theta_D.$$  \hspace{1.5cm} (11)

These considerations strongly suggest the need to study HTSCs in a more general framework of $\mu$-incorporated equations that are not constrained by the above inequality. Some of these equations are already available for studying pairing in the OPEM scenario; as was noted above, they were obtained in studies concerned with crossover physics and the superconductivity of SrTiO$_3$. In this section we give a complete account of such equations in the OPEM scenario.

In the OPEM scenario, the $\mu$-incorporated GBCSE at $T = 0$ for $|W_{10}|$ (which is used interchangeably with $\Delta_{10}$ in the equations below) is [7]

$$1 = \frac{V_f}{4\pi} \left[ I_{11}(\mu_0, |W_{10}|) + I_{12}(\mu_0, |W_{10}|) \right].$$  \hspace{1cm} (12)
where \( V_0 \) is the BCS interaction parameter as in \( N(0)V \) and \( \mu_0 \) the chemical potential at \( T = 0 \), and

\[
I_{11}(\mu_0, |W_{10}|) = -\left(\frac{2m}{\hbar^2}\right)^{3/2} \int_{-k_\theta_0}^{k_\theta_0} d\xi \sqrt{\xi^2 + \mu_0} \frac{\sqrt{\xi^2 + \mu_0}}{\xi - |W_{10}|/2},
\]

\[
I_{12}(\mu_0, |W_{10}|) = \left(\frac{2m}{\hbar^2}\right)^{3/2} \int_0^{k_\theta_0} d\xi \sqrt{\xi^2 + \mu_0} \frac{\sqrt{\xi^2 + \mu_0}}{\xi + |W_{10}|/2}.
\]

Substituting these into Equation (12) and multiplying with \( \text{Fe}^{(0)} \), we have

\[
\left[ E_F(0) \right]^{3/2} = \frac{\lambda_0}{2} I_1(\mu_0, |W_{10}|),
\]

where

\[
\lambda_0 = \left(\frac{2m}{\hbar^2}\right)^{3/2} \frac{E_F^{(0)}}{4\pi^2} V_0 \]

and

\[
I_1(\mu_0, |W_{10}|) = I_{11}(\mu_0, |W_{10}|) + I_{12}(\mu_0, |W_{10}|)
\]

\[
= \int_{-k_\theta_0}^{k_\theta_0} d\xi \sqrt{\xi^2 + \mu_0} \frac{\sqrt{\xi^2 + \mu_0}}{\xi - |W_{10}|/2}.
\]

From the following relations involving the number density of conduction electrons and other relevant parameters

\[
n = \left(\frac{2m}{\hbar^2}\right)^{3/2} \int_{-\mu_0}^{\mu_0} d\xi \sqrt{\xi^2 + \mu_0} \left[1 - \frac{\xi}{\sqrt{\xi^2 + W_{10}^2}}\right]
\]

\[
n = \left[\frac{2mE_F(0)}{3\pi^2}\right]^{3/2},
\]

we obtain

\[
E_F^{3/2}(0) = \frac{3}{4} I_2(\mu_0, |W_{10}|),
\]

where

\[
I_2(\mu_0, |W_{10}|) = \int_{-\mu_0}^{\mu_0} d\xi \sqrt{\xi^2 + \mu_0} \left[1 - \frac{\xi}{\sqrt{\xi^2 + W_{10}^2}}\right]
\]

\[
= \frac{4}{3} (\mu_0 - k_\theta_0) \frac{3}{2} + \int_{-k_\theta_0}^{k_\theta_0} d\xi \sqrt{\xi^2 + \mu_0} \left[1 - \frac{\xi}{\sqrt{\xi^2 + W_{10}^2}}\right].
\]

The last step is a consequence of splitting the region of integration into two parts (when \( \mu_0 > k_\theta_0 \)) \(-\mu_0\) to \(-k_\theta_0\) and \(-k_\theta_0\) to \(k_\theta_0\); in the first part \( |W_{10}| = 0 \) whence the expression in the square brackets in the integrand reduces to 2.

From Equations (13) and (16) we obtain

\[
\frac{\lambda_0}{2} I_1(\mu_0, |W_{10}|) - \left[\frac{3}{4} I_2(\mu_0, |W_{10}|)\right]^{3/2} = 0.
\]
Equation (18), valid at $T = 0$, is one of our basic equations. Given below from [8] is another basic equation which is valid at $cT = 0$:

\[
\lambda_1 \frac{3}{4} I_4(\mu, T_c) \left[ \frac{3}{4} I_4(\mu, T_c) \right]^{1/3} = 0,
\]

where

\[
\lambda_1 = \left[ \frac{(2m/h^2)^{3/2} E_F(T_c)}{4\pi} \right],
\]

\[
I_3(\mu, T_c) = \int d\xi \sqrt{\xi + \mu} \tanh\left( \frac{\xi}{2k_BT_c} \right)
\]

and

\[
I_4(\mu, T_c) = \int d\xi \sqrt{\xi + \mu} \left[ 1 - \tanh\left( \frac{\xi}{2k_BT_c} \right) \right].
\]

In the above equations $\mu_1$ is the chemical potential and $V_1$ the value of $V$ in $[N(0)V]$ at $T = T_c$. If $\mu_1$ and $T_c$ are known, then we can determine $E_F(T_c)$ via

\[
E_F(T_c) = \left[ \frac{3}{4} I_4(\mu, T_c) \right]^{2/3}.
\]

3.2. $\mu$-Incorporated GBCSEs in the Two-Phonon Exchange Mechanism (TPEM) Scenario for a Composite SC

Equations (18) and (19) can be generalized to the TPEM scenario by replacing the “propagator” $V$ used in the former scenario by a “superpropagator” $(V_1 + V_2)$ [2] [16], where $V_1 \neq 0$ for electrons in the energy range $-kBT_1$ to $kBT_1$ and $V_2 \neq 0$ in the range $-kBT_2$ to $kBT_2$; otherwise these interaction parameters have vanishing values. Following then the procedure given in [16], we obtain for LCO (which we recall involves only one interaction parameter) the following equation as generalization of Equation (18)

\[
\lambda_2 \frac{3}{4} I_4^{(2)}(\theta_1, \theta_2, \mu_0, |W_{20}|) \left[ \frac{3}{4} I_4^{(2)}(\theta_2, \mu_0, |W_{20}|) \right]^{1/3} = 0,
\]

where the superscript $(2)$ of a symbol denotes that it pertains to the TPEM scenario, and

\[
I_4^{(2)}(\theta_1, \theta_2, \mu_0, |W_{20}|) = \int d\xi \sqrt{\xi + \mu_0} \left[ 1 - \tanh\left( \frac{\xi}{2k_BT_2} \right) \right]
\]

\[
= \frac{4}{3} \left( \mu_0 - k_BT_2 \right)^{1/2} + \int d\xi \sqrt{\xi + \mu_0} \left[ 1 - \tanh\left( \frac{\xi}{2k_BT_2} \right) \right].
\]

In these equations $\theta_1$ and $\theta_2$ are the values of $\theta_1(\Lambda_D)$ given in Equations (3) and (4), respectively, and the upper limit of the number equation has been taken as the greater of the two Debye temperatures so that pairing can take place due to both the sub-lattices.

Similarly, we obtain the desired generalization of Equation (19) as
\[
\frac{\lambda_0}{2} I_{3}^{(2)} (\theta_1, \theta_2, \mu, T_c) - \left[ \frac{3}{4} I_{4}^{(2)} (\theta_2, \mu_1, T_c) \right]^{(3)} = 0,
\]

where

\[
I_{3}^{(2)} (\theta, \mu, T_c) = \int \frac{d\xi}{\xi} \sqrt{\xi + \mu} \tanh \left( \frac{\xi}{2k_B T_c} \right) + \int \frac{d\xi}{\xi} \sqrt{\xi^2 + \mu} \tanh \left( \frac{\xi}{2k_B T_c} \right)
\]

and

\[
I_{4}^{(2)} (\theta_2, \mu_1, T_c) = \int \frac{d\xi}{\xi} \sqrt{\xi + \mu_1} \left[ 1 - \tanh \left( \frac{\xi}{2k_B T_c} \right) \right].
\]

3.3. An Explanation of the Result \(2 |W_{20}| / k_B T_c = 4.27\) for LCO on the Basis of Equations (24) and (27) and a Tenet of BCS Theory

While our treatment of the pairing problem in both OPEM and TPEM scenarios has been perfectly general, it has led to an undetermined set of equations. In the latter case we have only two equations, Equations (24) and (27), containing six variables: \(\lambda_0, \lambda_1, \mu_0, \mu_1, W_{20}, \) and \(T_c\). Therefore we now assume

\[
\lambda_0 = \lambda_1, \mu_0 = \mu_1 = \mu.
\]

We could have made this assumption at the outset because it is in accord with a tenet of BCS theory. We chose not to do so in order to have readily available a set of equations that might be useful, should it be considered worthwhile to follow up this work with one of greater generality. All calculations in the following are carried out by assuming Equation (30).

Since Equations (24) and (27) are the \(\mu\)-incorporated versions of Equations (8) and (5), respectively, we need to show that when the constraint embodied in Equation (11) is imposed they yield solutions in agreement with those obtained by solving the latter equations. To this end, we solve Equation (27) for \(\lambda\) with the input of \(\theta_1 = 104.8\) K, \(\theta_2 = 431.1\) K (see Equations (3) and (4)), \(T_c = 38\) K and different values of \(\mu\). We begin with \(\mu = 300 k_B \theta_2\), which manifestly satisfies Equation (11), and find that \(\lambda = 0.26818\), which is the result that we had obtained earlier via Equation (5) and noted in Equation (6). Solution of Equation (24) with \(\mu = 300 k_B \theta_2\), and \(\lambda = 0.26818\) then yields \(W_{20} = 6.995\) meV, or \(2 |W_{20}| / k_B T_c = 4.27\), which also agrees with the result obtained earlier via Equation (8) and noted in Equation (9). Having thus established that Equations (24) and (27) satisfy the requisite consistency condition, repeating the exercise just carried out by progressively decreasing \(\mu\) we find that (a) all results quoted for \(\mu = 300 k_B \theta_2\) remain unchanged for values of \(\mu\) up to \(\approx 40\) meV, and (b) for the limiting value of \(\mu = k_B \theta_2 = 37.15\) meV (note that any value lower than this will cause \(I_{3}^{(2)} (\theta_2, \mu, T_c)\) to become complex – see Equation (28)), the results are: \(\lambda = 0.27507\), \(W_{20} = 6.953\) meV, or \(2 |W_{20}| / k_B T_c = 4.25\).

Even after incorporating \(\mu\) in the equations for \(T_c\) and \(\Delta\), our considerations so far have succeeded in explaining only one of the observed values of the gap-to-\(T_c\) ratio for LCO. Therefore there would seem to be a need for a new idea to explain the other values. It seems to us that the recent findings of Tacon et al. [9] provide precisely such an idea, even though they are based on experiments carried out with another HTSC (YBa_2Cu_3O_{6.6}). Appealing to it while solving Equations (24) and (27), we present in the next section a complete solution of the problem being addressed.

3.4. An Explanation of the Different Reported Values of \(2 |W_{20}| / k_B T_c\) for LCO Based on a Treatment of the Number Equations at \(T = T_c\) and \(T = 0\) in the Light of the Experimental Findings of Tacon et al. [9]

The work reported in this section is based on an idea inspired by Tacon et al.’s experimental findings about the role of low-energy phonons in YBa_2Cu_3O_{6.6} (superconducting transition temperature \(T_c = 61\) K) determined by employing high-resolution inelastic X-ray scattering. These experiments revealed features that were interpreted by the authors as signifying that (a) extremely large superconductivity-induced line-shape renormalizations are caused by phonons in a narrow range of momentum space and (b) the electron-phonon interaction has sufficient strength to generate various anomalies in electronic spectra, but does not contribute significantly to Cooper
pairing. Having probed the electron-phonon coupling via their ingenious two-level approach of X-ray scattering, they further noted that “in terms of its amplitude, the coupling is actually by far the biggest ever observed in a superconductor, but it occurs in a very narrow region of phonon wavelengths and at a very low energy of vibration of the atoms”. This statement induces us to review below our earlier treatment of the number equation.

We recall that the limits of the number equation in the previous section—both at $T = T_c$ and $T = 0$—were taken as $-\mu$ and $k_BT_2$. We now call attention to the facts that a) in dealing with an SC that has $T_c \approx 38$ K, we need to invoke TPEM, which b) brings into play two Debye temperatures $\theta_1$ and $\theta_2 > \theta_1$, and c) if the SC were a 1-component SC characterized by $\theta_1$, the number equation at $T = 0$ for it would comprise two terms: one corresponding to where $|W_{10}| = 0$ for electrons having energies between $-\mu$ and $-k_BT_1$ and the other where $|W_{10}| \neq 0$ for energies between $-k_BT_1$ and $+k_BT_1$ (see Equation (17)); similarly, if the SC was a 1-component SC characterized by $\theta_2$, the number equation for it at $T = 0$ would comprise two terms, one corresponding to where $|W_{10}| = 0$ for energies between $-\mu$ and $-k_BT_2$ and the other where $|W_{10}| \neq 0$ for energies between $-k_BT_2$ and $+k_BT_2$. Note that the lower limit in both these cases is $-\mu$. In dealing with a composite SC characterized by two Debye temperatures $\theta_1$ and $\theta_2 > \theta_1$, it was then natural to take $k_BT_2$ as the upper limit of the number equation, and this is the choice we had made earlier.

Guided by the insight provided by the findings of Tacon et al. [9], we now proceed to explore the consequences of narrowing down the range of phonon energies in the problem. If we require that in doing so we should keep intact for both the sub-lattices the region of momentum space for which $|W_{20}| = 0$, then using these $(\lambda, \mu)$ solutions corresponding to the four specific values of $\lambda$, we have given the $(\lambda, \mu)$ values to solve Equation (24) for $|W_{20}| = 0$. We now follow up on this idea.

Our procedure above comprised solving Equation (27) for $\lambda$ with the input of $T_c$ and different values of $\mu$ and then using these $(\lambda, \mu)$ values to solve Equation (24) for $|W_{20}|$. We now adopt a variant of this procedure which comprises (a) eliminating $\lambda$ from Equations (24) and (27) by appealing to Equation (30), (b) solving the resulting equation for $\mu$ with the input of $T_c = 38$ K and $|W_{20}| = p_\lambda k_BT_c^2/2$ with $p$ as a variable, and then (c) determining $\lambda$ by using either Equation (24) or (27). This is a procedure that enables us to find quickly if sensible solutions for $(\lambda, \mu)$ exist for any particular value of $p$.

Eliminating $\lambda$ from Equations (24) and (27) by appealing to Equation (30), we have

$$\left[\frac{I_1^{(2)}(\theta_2, \mu, I_2^{(1)}(\theta_1, \mu, W_{20}))}{I_1^{(1)}(\theta_1, \theta_2, \mu, W_{20})}\right]^{\frac{3}{2}} = \left[\frac{I_2^{(2)}(\theta_2, \mu, T_c)}{I_2^{(1)}(\theta_2, \mu, T_c)}\right]^{\frac{3}{2}}. \tag{31}$$

Attempting to solve Equation (31), we find that it has no solution for $p \leq 4.2$. The solutions for $\mu$ for $4.3 \leq p \leq 9.5$ have been shown in Figure 1. The $\mu$ values of this figure are used to calculate the coupling strength $\lambda$ [with the additional input of $\theta_1 = 104.8$ K, $\theta_2 = 431.1$ K, and $T_c = 38$ K] via Equation (24) whence it is found to lie in the range 0.27388 - 0.26843. The resulting plot of $\lambda$ against $p$ is shown in Figure 2. In Table 2, we have given the $(\mu, \lambda)$ solutions corresponding to the four specific values of $p$, i.e., 4.3, 7.1, 8, and 9.3, that were mentioned in [6]. These results change insignificantly if $T_c$ is taken as 36 K or 40 K (rather than 38 K) as is seen from the following examples:

$$\begin{align*}
\mu &= 40.73 \text{ meV} & \mu &= 164.1 \text{ meV} \\
T_c &= 36 \text{ K} & T_c &= 40 \text{ K}
\end{align*}$$

4. Predictions of the $\mu$-Incorporated GBCSEs for LCO

4.1. Values of the Smaller Gaps

A review of our procedure so far is as follows. By including $\mu$ in GBCSEs as applicable to LCO, appealing to an idea inspired by the work of Tacon et al. [9] and using as input any of the observed values of the gap-to-$T_c$ ratio for $36 \leq T_c \leq 40$ K, we have been led to solutions for $\mu$ and $\lambda$ that are “sensible”. Sensible because we found a) $\mu$ to have a low value—in the meV range (recall that for elemental SCs, $\mu$ is in ~2 - 10 eV range), which is in accord with the assertion made in [14] and the values reported in [15], and b) $\lambda$ to be less than 0.5, which is in accord with the Bogoliubov constraint as discussed in [5].
Figure 1. Plot of the chemical potential $\mu$ (meV) for different values of $p$ obtained by solving Equation (30) with the input of $\theta_1 = 104.8$ K, $\theta_2 = 431.1$ K, $T_c = 38$ K, and $p = 2|W_{02}|/k_B T_c$.

Figure 2. Plot of the coupling strength $\lambda$ against $p$ obtained by solving Equation (24) with the input of $\mu$ values from the $(\mu, p)$ plot of Figure 1, $\theta_1 = 104.8$ K, $\theta_2 = 431.1$ K, and $T_c = 38$ K.
157

Table 2. Values of $\mu$ obtained by solving Equation (31) in the TPEM scenario with the input of $\theta_1 = 104.8$ K, $\theta_2 = 431.1$ K, $T_c = 38$ K, $|W_{lo}| = p k_s T_c/2$ (p = 4.3, 7.1, etc.) and the corresponding values of $\lambda$ calculated via Equation (24) or (27). Each pair of these ($\mu$, $\lambda$) values is then used to calculate $|W_{lo}|$ in the OPEM scenario by using Equation (18), first by taking $\theta$ as 104.8 K and then 431.1 K. Adjacent to each value of $|W_{lo}|$ is given in parentheses the temperature at which it is calculated via Equation (19) to vanish. In the columns following these values are given the corresponding gap-to-$T_c$ ratios with $T_c$ taken as 38 K, i.e., the temperature at which the larger gap vanishes.

We now note that the ($\mu$, $\lambda$)-values that we have been led to, enable us to calculate $|W_{lo}|$ and $T_c$ in the OPEM scenario vide Equations (18) and (19), respectively. These results, which constitute predictions of our approach, are also included in Table 2. It thus follows that, in suitably sensitized experimental set-ups, LCO should also exhibit for the gap-to-$T_c$ ratio (with $T_c$ taken as 38 K) the following values: $0.27 - 0.29$ ($\approx 3$ K) and $1.12$ ($\approx 12$ K), where the numbers in the parentheses denote the temperatures at which these smaller gaps are predicted to vanish.

4.2. Carrier Concentration

We can calculate the carrier concentration $n$ via the following equation

$$n = \left( \frac{2m\mu}{\hbar^2} \right)^{3/2} \frac{1}{3\pi^2},$$

(32)

which is the second equation after Equation (15), with $E_F$ replaced by $\mu$ and the factor of $\hbar^2$ inserted. However, before we can use this equation we need to find the band effective mass of electrons in LCO. This can be done by using the following expressions for $N(0)$ as in $\lambda = \left[ N(0)V \right]$

$$N(0) = \frac{1}{4\pi^2} \left( \frac{2s m_e}{\hbar^2} \right)^{3/2} \mu^{1/2},$$

(33)

where we have put the band effective mass as $s$ times the free electron mass $m_e$, and

$$N(0) = \frac{3\gamma}{2\pi^2 k_B^2 v} \equiv \rho,$$

(34)

where $\gamma$ is the experimentally obtained electronic specific heat constant (also known as the Sommerfeld constant) and $v$ the gm-at volume.

From Equations (33) and (34) we obtain

$$s = \frac{\hbar^2}{2m_e} \left( \frac{4\pi^2 \rho}{\mu^{1/2}} \right)^{2/3}.$$  

(35)

We now use: $\gamma = 4.5$ mJ/mol K$^2$ (given in [11]), $v(La) = 22.60$ cm$^3$ and the values of $\mu$ corresponding to $p = 4.3$ and 9.3 to obtain

$$s(\mu = 39.72 \text{ meV}) = 11.2, \quad s(\mu = 165.2 \text{ meV}) = 6.96$$

(36)
Upon putting $m = s$ times the free electron mass in Equation (32) we obtain

For $\mu = 39.72$ meV, $n = 1.35 \times 10^{21}$ cm$^{-3}$

For $\mu = 165.2$ meV, $n = 5.60 \times 10^{21}$ cm$^{-3}$

(37)

Since the value of the carrier concentration noted in [6] is “of the order of $10^{21}$/cm$^3$,” these results support the approach followed in this study.

5. Discussion

1) Strictly speaking, Fermi energy is a term applicable to non-interacting systems. In this note however it has been used interchangeably with the chemical potential, as is usually done in the literature on superconductivity.

2) It is well known that HTSCs are characterized by multiphase and multi-scale complexity and that their Fermi surfaces have highly complex structures comprising many sheets that span different bands. In the light of this observation it would seem that our treatment of LCO based on multiple Debye temperatures and TPEM is rather naive. We are therefore impelled to draw attention to the following:

a) As can be seen in [17], Fermi surfaces of elemental SCs too have rather complex structures: none of them has the idealized spherical Fermi surface assumed in BCS theory. And yet, with the exception of a few, e.g., Pb and Hg, the mean-field approximation (MFA) employed in the theory works for most of them.

b) It is evident that the values of $\mu$ corresponding to different values of $\Delta$ and $T_c$ that we have determined reflect the structure of the Fermi surface of the SC. Implicit in our approach is the concept of locally spherical Fermi surfaces (LSFSs), which takes the complexity of the HTSC into account in a rather simple (if not the simplest possible) manner. Such simplicity of approach for the kind of system we are dealing with is a goal every model strives to achieve. We note that LSFSs come into play because of itinerancy of electrons and the adoption of MFA.

c) Itinerancy of electrons in a multi-band SC is a much-invoked concept since at least the time of Suhl et al.’s paper [18]. We give below an analogy to bring out how this concept justifies dropping of the first term in the number equation (26).

d) Consider a convoy on a road passing through a range of mountains. As the road twists and turns through a series of valleys and mountains, the amount of sunlight it receives will vary from a maximum at the highest point of the range to a minimum at a place determined by the topography of the entire range. Itinerant conduction electrons in a solid on a 3-D Fermi surface are akin to such a convoy: there will be places where they can exchange phonons with the A- or the B-ions separately, and a place or places where they can exchange phonons with both of them simultaneously. For the last of these cases, one can then envisage a situation where phonon energies span not the usual range from $-\mu$ to $k_B\theta$, but a depleted range from $-k_B\theta_2$ to $k_B\theta_2$. The mean value of $\mu$ for the electrons under consideration is equivalent to the word “place” used for the convoy.

e) It seems interesting to point out that the concept of LSFSs is similar to the concept of locally inertial coordinate frames employed in the general theory of relativity [19].

3) In connection with the remark by Tacon et al. [9] that “the electron-phonon interaction has sufficient strength to generate various anomalies in electronic spectra, but does not contribute significantly to Cooper pairing”, we should like to note that this statement is presumably based keeping OPEM in mind, which cannot account for the observed $T_c$ of LCO.

6. Conclusions

Our findings provide a confirmation of the idea that low values of $\mu$ play an important role in HTSCs. Besides, we have for the first time given a plausible quantitative explanation of the different values of gap-to-$T_c$ ratio that have been reported for LCO in the literature.

In effect, the approach followed in this note can also be viewed as a new direct method for relating the $\Delta_0$ and $T_c$ of an HTSC with its $E_F$.
