Abstract

The unsteady pulsatile flow of blood through porous medium in an artery has been studied under the influence of periodic body acceleration and slip condition by considering blood as incompressible Newtonian electrically conducting fluid in the presence of magnetic field. In this paper, a new technique of differential quadrature method is introduced to find numerical solution of nonlinear partial differential equations such as the equation of motion of this problem “Navier-Stokes equation”. The presence of the nonlinearity in the problem leads to severe difficulties in the solution approximation. In construction of the numerical scheme “a new algorithm” a generalized differential quadrature method (GDQM) is to use for derivatives with respect to space variables of differential equations and for the time derivative applying fourth order Runge-Kutta Method (RKM). The GDQM changed the nonlinear partial differential equations into a system of nonlinear ordinary differential equations (ODEs). The obtained system of ODEs is solved by 4th order RKM. This combination of DQM and 4th order RKM gives a very good numerical technique for solving time dependent problems. The algorithm is coded in Matlab 7.14.0.739 and the simulations are run on a Pentium 4 CPU 900 MHz with 1 GB memory capacity. The effects of slip condition, magnetic field, porous medium, and body acceleration have been discussed. The numerical results show that the proposed method is more accurate and convergent than other numerical methods in literature. The method is illustrated and compared with the exact and analytical solutions and it is found that the proposed method gives a better accuracy and is quite easy to implement.

1. Introduction

Numerical approximation methods for solving partial differential equations have been widely used in many fields of science, particularly in physics, engineering, chemistry and finance, and are fundamental for the mathematical formulation of continuum models. Most numerical simulations of engineering problems can be currently carried out by conventional low order, classical techniques, such as finite element and finite difference methods are well developed and well known. These methods can provide very accurate results by using a large number of grid points. However, in some practical applications, the numerical solutions of partial differential equations are required at only a few specified points in the physical domain. For acceptable accuracy, the conventional low order technique still required the use of a large number of grid points to obtain accurate solutions at these specified points. In seeking a more efficient method using just a few grid points to obtain accurate numerical results, the technique of differential quadrature method (DQM) was proposed by Bellman [1] [2]. The DQM is a numerical solution technique for initial and/or boundary value problems. The DQM is an easy and efficient numerical method for the rapid solution of various linear and nonlinear differential and integro-differential equations. The DQM circumvents the above difficulties by computing a moderately accurate solution from only a few points. For more details see [3]. The DQM follows the concepts of classical integral quadrature. The DQM discretizes any derivative at a point by a weighted linear sum of functional values at its neighboring points. The key to DQ is to determine the weighting coefficient for any order derivative discretization. Bellman et al. [2] suggested two methods to determine the weighting coefficients of the first order derivative. The first method used a simple function as test functions to solve an algebraic equation system. The second method is similar to the first one with the exception, but with the coordinates of grid points chosen as the roots of the shifted Legendre polynomial. Most pervious application of DQ in engineering use Bellman’s first method to obtain the weighting coefficients because it lets the coordinates of grid points be chosen arbitrarily. Unfortunately, when the order of the algebraic equation system is large, its matrix is ill-conditioned. Thus it is very difficult to obtain the weighting coefficients for a large number of grid points using this method. To overcome the drawbacks of the above methods, Quan and Chang [4], Shu and Richards [5] and Wen and Yu [6] derived a recursive formula to obtain these coefficients directly and irrespective of the number and positions of the sampling points. In their approach, they used the Lagrange polynomials as the test functions and found a simple recurrence formula for the weighting coefficients for the first and second order derivatives discretization. More generally, Shu and Richards [7], and Shu [8] present the generalized differential quadrature (GDQ). In GDQ, the weighting coefficients of the first order derivative are determined by a simple algebraic formulation without any restriction on the choice of grid points, and the weighting coefficient of the second and higher order derivatives are determined by a recurrence relationship. The major advantage of GDQ over DQ is its ease of the computation of the weighting coefficients without any restriction on the choice of grid points. The pioneer works for the applications of the DQM to the general area of structural mechanics and fluid mechanics. To solve these equations, the boundary conditions have to be implemented appropriately. For the case where there is only one boundary condition at each boundary, the implementation is very simple and can be done in a straightforward way. However, in some cases, there is more than one boundary condition, which could result in difficulties in the numerical implementation of the boundary conditions. One example is the solution of Navier-Stokes equations in fluid mechanics. Another example is the flexural vibration analysis of a thin beam or a plate. Like some other numerical methods, the GDQM discretizes the spatial derivatives and, therefore, reduces the partial differential equations into a set of algebraic equations. To solve these equations, the boundary conditions have to be implemented appropriately. The details of the DQM and its applications can be found in [3] [9]-[16]. AL-SAIF and Zheng-You [17] presented improve to the traditional DQM by using the upwind difference scheme for the convective terms to solve the coupled two-dimensional incompressible Navier-Stokes equations and heat equation. The results show that the new method is more accurate, and has better convergence than the conventional DQM for numerically computing the steady-state solution. AL-SAIF and Zheng-You [18] studied the two-dimensional steady flow of an incompressible second-order viscoelastic fluid between two parallel plates. By using the DQM with only a few grid points, the high-accurate numerical results were obtained.
The investigations of blood flow through arteries are of considerable importance in many cardiovascular diseases particularly atherosclerosis. Under normal conditions, blood flow in the human circulatory system depends upon the pumping action of the heart and this produces a pressure gradient throughout the arterial network. During recent years, the effect of magnetic field on the flow has been studied. MHD viscous flow though pipes plays significant role in different areas of science and technology such as Petroleum industry, Biomechanics, Drainage and Irrigation engineering and so on. The electromagnetic force (Lorentz force) acts on the blood and this force opposes the motion of blood and there by flow of blood is impeded, so that the external magnetic field can be used in the treatment of some kinds of diseases like cardiovascular diseases and in the diseases with accelerated blood circulation such as hemorrhages and hypertension. Earlier studies in flow in porous media have revealed the Darcy law which relates linearly the flow velocity to the pressure gradient across the porous medium. An important characteristic for the combination of the fluid and the porous medium is the tortuosity which represents the hindrance to fluid diffusion imposed by local boundaries or local viscosity.

No slip boundary conditions are a convenient idealization of the behavior of viscous fluids near walls. The inadequacy of the no-slip condition is quite evident in polymer melts which often exhibit microscopic wall slip. The slip condition plays an important role in shear skin, spurt, and hysteresis effects. The boundary conditions relevant to flowing fluids are very important in predicting fluid flows in many applications. The fluids that exhibit boundary slip have important technological applications such as in polishing valves of artificial heart and internal cavities.

In situations like travel in vehicles, aircraft, operating jackhammer, and sudden movements of body during sports activities, the human body experiences external body acceleration. Prolonged exposure of a healthy human body to external acceleration may cause serious health problem like headache, increase in pulse rate and loss of vision on account of disturbances in blood flow.

Many mathematical models have already been investigated by several research workers to study the unsteady pulsatile blood flow through porous medium under the influence of periodic body acceleration in the presence of magnetic field with slip boundary condition numerically and analytically. El-Shehawey et al. [19]-[22] studied the effect of body acceleration in different situations. They studied the effect of MHD flow of blood under body acceleration and the Womersley problem for pulsatile flow of blood through a porous medium. The blood flow through porous medium under periodic body acceleration has been studied. The analytical solutions of all above cases are obtained by using Laplace and finite Hankel transforms. El-Shehawey et al. [23] studied the pulsatile flow through a porous medium under the influence of body acceleration. An analytical solution is obtained by using Laplace and finite Hankel transforms. El-Shahed [24] studied pulsatile flow of blood through a stenosed porous medium under the influence of periodic body acceleration. Analytical solution is obtained by using Laplace and finite Hankel transforms. El-Shehawey et al. [25] studied the slip effects on the peristaltic flow of a non-Newtonian Maxwellian fluid. The Navier-Stokes equations are solved by using a perturbation analysis. Sanyal and Debnath [26] presented a mathematical model for studying the effect of magnetic field on pulsatile blood flow through an inclined circular tube with periodic body acceleration. The analytical solution is obtained by using Finite Hankel and Laplace transforms. Das and Saha [27] studied the arterial MHD pulsatile blood flow through a stenosed porous medium with periodic body acceleration. An analytical solution is obtained using Finite Hankel and Laplace transforms. Sanyal and Biswas [28] studied the effect of uniform transverse magnetic field on its pulsatile motion through an axisymmetric tube by assuming blood as incompressible biviscous fluid. The problem is solved by Perturbation technique with small amplitude of pulsation. Mathur and Jain [29] studied the pulsatile flow of blood through stenosed arteries, including the effects of body acceleration and a magnetic field. An analytical solution is obtained by using Hankel and Laplace transforms. Misra et al. [30] presented a mathematical modeling of blood flow in porous vessel having double stenosis in the presence of an external magnetic. This model is consistent with the principles of ferro-hydrodynamics and magnetohydrodynamics. Eldesoky [31] presented a mathematical analysis of unsteady blood flow through parallel plate channel under the action of an applied constant transverse magnetic field. Eldesoky [32] studied the effects on the unsteady MHD pulsatile blood flow through porous medium in an artery under the influence of body acceleration. An analytical solution is obtained by applying the Laplace transform. Mohan et al. [33] investigated the effect of magnetic field on blood flow in cylindrical artery through porous medium. An analytical solution is obtained by applying Laplace transforms and Finite Hankel Transforms. Tzirtzilakis [34] studied a mathematical model of biomagnetic fluid dynamics (BFD) under the action of magnetic field. The numerical results are obtained using a Finite Differences technique based on a pressure-linked pseudotransient method on a collocated grid. Mokhtar
study the unsteady motion of the magneto-hydrodynamic biviscosity fluid with heat and mass transfer through a uniform porous medium between two permeable parallel walls, taking into account pulsation of the pressure gradient. A numerical solution of governing equations is obtained using a matching technique of a Runge-Kutta-Merson method and Newton iteration in a shooting. Malekzadeh [36] studied the influence of a magnetic field on the skin friction factor of steady fully-developed laminar flow through a pipe. A numerical solution of the governing equations is obtained by applying Finite Difference scheme. Sankar and Lee [37] developed a computational model to analyze the effects of magnetic field in a pulsatile flow of blood through narrow arteries with mild stenosis. Female Difference method is employed to solve the simplified nonlinear partial differential equation. Amira et al. [38] presented a mathematical model of Newtonian blood flow through the irregular stenosis to study the effect of body acceleration. A numerical solution of the equation of motion is obtained by applying a combination of a generalized differential quadrature method and 4th order Runge-Kutta method. Wang [40] presented exact solution of the Navier-Stokes equations of stagnation flows with slip.

In this paper, numerical solution using a new technique is applied to time dependent problem Navier-Stokes equations. Derivatives with respect to space variables are discretized using GDQMQ giving a system of ordinary differential equations for the time derivative, and time derivatives are discretized using 4th order RKM. A new technique gives a very good numerical solution for solving time dependent problems. Stability of 4th order RKM criteria is controlled with several values of time increment Δt and number of grid points N in space region. In this paper, GDQM used for studying the effect of slip condition on unsteady pulsatile blood flow through a porous medium under the influence of periodic body acceleration in the presence of magnetic field.

**2. Mathematical Formulation**

Consider the flow as shown in [32], blood is supposed to be as an electrically conducting, Newtonian, incompressible, and viscous fluid in the presence of magnetic field in an axisymmetric cylindrical artery of radius $R$ through porous medium with body acceleration. The fluid subjected to a constant magnetic field acts perpendicular to the artery. The slip boundary conditions are also taken into account. We assume that the magnetic Reynolds number of the flow is taken to be small enough, so that the induced magnetic and electric field can be neglected. We consider the flow as axially symmetric, pulsatile. The pressure gradient and body acceleration $G$ are given by:

$$-\frac{\partial p}{\partial z} = A_o + A_1 \cos(\omega_o t), \ t \geq 0,$$

$$G = a_o \cos(\omega_o t), \ t \geq 0,$$

where $A_o$ and $A_1$ are pressure gradient of steady flow and amplitude of oscillatory part respectively, $a_o$ is the amplitude of the body acceleration, $\omega_o = 2\pi f_p$, $\omega_b = 2\pi f_b$ with $f_p$ is the pulse frequency, and $f_b$ is the body acceleration frequency and $t$ is time.

The governing equation of the motion for flow in cylindrical polar coordinates is given by

$$\rho \frac{\partial u}{\partial t} = -\frac{dp}{dz} + \rho g + \mu \nabla^2 u - \frac{\mu}{k} u + J \times \vec{B}.$$  

Maxwell’s equations are

$$\nabla \cdot \vec{B} = 0, \nabla \times \vec{B} = \mu_0 J \times \vec{E} = -\frac{\partial \vec{B}}{\partial t}, \nabla \times \vec{E} = \frac{\rho_f}{\epsilon}.$$  

Ohm’s law is

$$\vec{J} = \sigma (\vec{E} + \nu \times \vec{B}).$$  

where $\nu = (0, 0, u)$ is the velocity distribution, $\rho$ the blood density, $\mu$ the dynamic viscosity of the blood, $\mu_0$ magnetic permeability, $\vec{B} = (0, B_y, 0)$ the magnetic field, $\vec{E}$ the electric field, $\rho_f$ the volumetric free charge density, $\epsilon$ is the dielectric constant, $J$ the current density, $k$ is the permeability parameter of porous medium,
and $\sigma$ the electric conductivity of the blood. For small magnetic Reynolds number, the linearized magnetohydrodynamic force $\mathbf{J} \times \mathbf{B}$ can be put into the following form:

$$
\mathbf{J} \times \mathbf{B} = -\sigma \mathbf{B}_0^2 \mathbf{u}.
$$

(6)

where $u(r,t)$ represents the axial velocity of the blood.

Under the above mentioned assumption, the equation of motion is:

$$
\rho \frac{\partial u}{\partial t} = A_0 + A_1 \cos(\omega_p t) + \rho \left( a_o \cos(\omega_t t) + \mu \left( \frac{\partial^2 u}{\partial r^2} + \frac{1}{r} \frac{\partial u}{\partial r} \right) \right) - \left( \frac{\mu}{k} \right) u - \sigma \mathbf{B}_0^2 \mathbf{u}.
$$

(7)

The boundary conditions that must be satisfied by the blood on the wall of artery are the slip conditions. For slip flow the blood still obeys the Navier-Stokes equation, but the no-slip condition is replaced by the slip condition $u_t = A_p \left( \frac{\partial u}{\partial n} \right)$, where $u_t$ is the tangential velocity, $n$ is normal to the surface, and $A_p$ is a coefficient close to the mean free path of the molecules of the blood [40] and then the boundary conditions on the wall of the artery are:

$$
u(\mathbf{r},t) = A_p \frac{\partial u(\mathbf{r},t)}{\partial r} \quad \text{at} \quad r = R, \quad \text{(Slip condition)}
$$

(8a)

$$
u(0,t) \quad \text{is finite at} \quad r = 0, \quad \text{(axis of the pipe)}
$$

(8b)

Let us introduce the following dimensionless quantities:

$$
u^* = \frac{u}{\omega R}, \quad r^* = \frac{r}{R}, \quad t^* = \frac{t}{\omega}, \quad \tau^* = \frac{z}{R}, \quad \kappa^* = \frac{k}{R^2},
$$

$$
A_o^*, \quad A_1^*, \quad A_p^* = \frac{R}{\mu \omega} A_o, \quad A_1^* = \frac{R}{\mu \omega} A_1, \quad b = \frac{\mu \omega}{\omega p}.
$$

(9)

The Hartmann number, $Ha$, the Womersley parameter, $\alpha$ and the Knudsen number, $k_n$ are defined respectively by:

$$
H_a = B_o R \sqrt{\frac{\sigma}{\mu}}, \quad \alpha = R \sqrt{\frac{\rho \omega}{\mu}}, \quad k_n = \frac{A}{R}.
$$

(10)

In terms of these variables, Equations (7) and (8) can be rewritten in the non-dimensional form after dropping the stars becomes:

$$
\alpha^2 \frac{\partial u}{\partial t} = A_o + A_1 \cos(\tau^*) + a_o \cos(b \tau^*) + \frac{\partial^2 u}{\partial r^2} + \frac{1}{r} \frac{\partial u}{\partial r} - \left( H_a^2 + \frac{1}{k_n} \right) u.
$$

(11)

Also the boundary conditions are:

$$
u(r,t) = k_n \frac{\partial u(r,t)}{\partial r} \quad \text{on} \quad r = 1,
$$

(12a)

$$
u(0,t) \quad \text{is finite (axis of the pipe)}
$$

(12b)

And the initial condition is:

$$
u(r,0) = 1 \quad \text{at} \quad t = 0
$$

(12c)

#### 3. Generalized Differential Quadrature Method (GDQM)

The DQM is a numerical solution technique for initial and/or boundary value problems. This technique has been successfully employed in a variety of problems in engineering and physical sciences. The DQM approximates the derivative of a function at any location by a linear summation of all the functional values along a mesh (grid) line. The GDQM is systematically employed to solve problems in Fluid mechanics, Vibration analysis and
Structural analysis. The technique of GDQM for the solution of partial differential equations extended and generalized. Numerical examples have shown the super accuracy, efficiency, convenience and the great potential of this method. A GDQM, which was recently proposed by Shu and Richards [7] [8] for solving partial differential equations in fluid mechanics. For the discretization of the first and higher order derivatives, the following linear constrained relationships are applied

\[
 f^{(n)}_i(x_t) = \sum_{j=1}^{N} C_{ij}^{(n)} \cdot f(x_j, t), \quad n = 1, 2, \cdots, N-1, \tag{13}
\]

For \( i = 1, 2, \cdots, N \); where \( f^{(n)}_i \) indicate \( n \)-th order derivatives of \( f(x, t) \) with respect to \( x \) at \( x_i \), \( N \) is the number of grid points in the whole domain. \( C_{ij}^{(n)} \) are the weighting coefficients. The key to DQ is to determine the weighting coefficients for the discretization of a derivative of any order. In order to find a simple algebraic expression for calculating the weighting coefficients without restricting the choice of grid meshes, Shu choose Lagrange interpolated polynomials as the tests functions. Shu and Richards [7] [8] gave a convenient and recurrent formula for determining the derivative weighting coefficients.

To determine the weighting coefficients of the GDQ method as:

Weighting coefficients for the first order derivative

\[
 C_{ij}^{(1)} = \frac{M^{(1)}(x_i)}{(x_i-x_j) \cdot M^{(1)}(x_j)} \quad i, j = 1, 2, \cdots, N \quad \text{and} \quad i \neq j \tag{14}
\]

\[
 C_{ii}^{(1)} = -\sum_{j=1, j \neq i}^{N} C_{ij}^{(1)}, \quad i = 1, 2, \cdots, N \tag{15}
\]

where

\[
 M(x) = (x-x_1)(x-x_2)\cdots(x-x_N) \tag{16.1}
\]

\[
 M^{(1)}(x) = \prod_{k=1, k \neq i}^{N} (x_i-x_k) \tag{16.2}
\]

Weighting coefficients for the second and higher order derivatives

\[
 C_{ij}^{(n)} = n \left( C_{ij}^{(1)} \cdot C_{ij}^{(n-1)} - C_{ij}^{(n-1)} \right) / (x_i-x_j), \quad \text{for} \quad j \neq i, i, j = 1, 2, \cdots, N; n = 2, 3, \cdots, N-1. \tag{17}
\]

\[
 C_{ii}^{(n)} = -\sum_{j=1, j \neq i}^{N} C_{ij}^{(n)}, \quad i = 1, 2, \cdots, N; n = 2, 3, \cdots, N-1. \tag{18}
\]

where \( C_{ij}^{(n)} \) and \( C_{ij}^{(n-1)} \) are the weighting coefficients of the \( n \)-th and the \( (n-1) \)-th derivatives. The \( C_{ii}^{(n)} \) can be obtained from a relationship similar to Equation (15). Thus Equations (17) and (18) together with Equations (14) and (15) give a convenient and general form for determining the weighting coefficients for the derivatives of orders one through \( N-1 \).

4. Numerical Discretization and Stability of the Scheme

In the present study, substituting the GDQ derivative approximations given in Equation (13) in the governing Equation (11). The coordinates of the grid points are chosen according to Chebyshev-Gauss-Lobatto by using \( N \) sampling as:

\[
 X(i) = \frac{1}{2} \left[ 1 - \cos \left( \frac{i-1}{N-1} \pi \right) \right], \quad i = 1, 2, 3, \cdots, N;
\]

The GDQM is applied for the discretization of space derivatives of the unknown function \( u \), we obtain the ordinary differential equation

\[
 a^2 \frac{\partial^2 u(r_i, t)}{\partial t^2} = A_0 + A_1 \cos(t) + a_G \cos(bt) + \sum_{j=1}^{N} C_{ij}^{(2)} \cdot u_j + \frac{1}{r_i} \sum_{j=1}^{N} C_{ij}^{(1)} \cdot u_j - \left( H_x^2 + \frac{1}{k} \right) u_i, \quad i = 1, 2, \cdots, N \tag{19}
\]
where \( u_i \), \( i = 1,2,\ldots,N \), is the velocity value at the grid \( r_i \cdot C_y^{(i)} \) and \( C_y^{(2)} \) are the weighting coefficient matrices of the first and second order derivatives.

Similarly, the derivatives in the boundary conditions can be discretized by the GDQM. As a result, the numerical boundary conditions can be written as:

\[
K_{i,j} \cdot u_i = k \sum_{k=1}^{N} C_{i,k}^{(0)} \cdot u_k \quad \text{(Slip conditions)}
\]

\[
\sum_{k=1}^{N} C_{i,k}^{(0)} \cdot u_k = 0
\]

Equation (20) can’t be easily substituted into the governing equation. However, we can give solutions, \( u_i \) and \( u_N \) as:

\[
u_i = R_1 \left[ \sum_{k=2}^{N+1} C_{i,k}^{(1)} \cdot u_k + R_3 \sum_{k=2}^{N+1} C_{i,k}^{(N)} \cdot u_k \right]
\]

\[
u_N = R_2 \left[ R_3 \sum_{k=2}^{N+1} C_{i,k}^{(1)} \cdot u_k + R_3 \sum_{k=2}^{N+1} C_{i,k}^{(N)} \cdot u_k \right]
\]

According to Equation (21), \( u_i \) and \( u_N \) are expressed in terms of \( u_2,u_3,\ldots,u_{N-1} \) and can be easily substituted into the governing Equation (19). In total we have \( N \) unknowns \( u_2,u_3,\ldots,u_{N-1} \). In order to close the system, the discretized governing Equation (19) has to be applied at \( N-2 \) mesh points. This can be done by applying Equation (19) at grid points \( r_2,r_3,\ldots,r_{N-1} \) Substituting Equation (21) into Equation (19) gives:

\[
\alpha \frac{\partial u_i(r,t)}{\partial t} = A_o + A_1 \cos(t) + a_o \cos(ht) + \sum_{j=2}^{N+1} C_{i,j}^{(0)} \cdot u_j + \frac{1}{r_i} \sum_{j=2}^{N+1} C_{i,j}^{(1)} \cdot u_j - \left( \frac{H}{k} + \frac{1}{k} \right) u_i,
\]

\( i = 2,3,\ldots,N-1 \)

It is noted that Equation (22) has \( N-2 \) equations with \( N-2 \) unknowns.

Now, the discretization for time derivative will be performed by using Runge-Kutta Method. Now, \( \frac{\partial u_i}{\partial t} \) is also considered discretized as \( \frac{\partial u_{ij}}{\partial t} \), thus Equation (22) is a set of DQ algebraic equations which can be written in a matrix form

\[
[A] \{u\} = \{b\},
\]

where \( \{u\} = \{u_2,u_3,\ldots,u_{N-1}\} \) is a vector of unknown \( N-2 \) functional values at all discretized points of the region, \([A]\) is the \((N-2) \times (N-2)\) coefficient matrix, and the right hand side vector \( \{b\} \) of size \((N-2) \times 1\) contains first order time derivatives of the function \( u \) at the same discretized points. Therefore a numerical scheme is necessary for handling these time derivatives. Equation (23) can be solved by several time integration schemes such as Euler, Modified Euler, and Runge-Kutta Methods. Here, Runge-Kutta Method is going to be used since it is a one step method obtained from the Taylor series expansion of \( u \) up to and including the terms involving \( g(\Delta t)^n \) where \( \Delta t \) is the step size with respect to time. The \( 4^{th} \) order RKM since its stability region is larger comparing to the other time integration methods and simple for the computations.

The \( 4^{th} \) order RKM is applied to discretized time derivatives in the resulting system of algebraic Equation (23). RKM is a one step method for solving initial value problems. Therefore the resulting algebraic system of Equation (23) can originally be considered as an initial value problem in the form (a set of ordinary differential equations in time)

\[
\{b\} = \frac{d\{u\}}{dr} = [A] \{u\}
\]

Thus the \( 4^{th} \) order RKM gives for the governing equation the following vector equation

\[
\{u_{n+1}\} = \{u_n\} + \frac{\Delta r}{6} \left[ \{K_1\} + 2 \{K_2\} + 2 \{K_3\} + \{K_4\} \right]
\]
where:

\[
K_1 = f\left(t_{n}, u_{n}\right),
\]

\[
K_2 = f\left(t_{n} + \frac{\Delta t}{2}, u_{n} + \frac{\Delta t}{2} K_1\right),
\]

\[
K_3 = f\left(t_{n} + \frac{\Delta t}{2}, u_{n} + \frac{\Delta t}{2} K_2\right),
\]

\[
K_4 = f\left(t_{n} + \Delta t, u_{n} + \Delta t K_3\right).
\]

Applying 4th order RKM Equation (25) in Equation (24). Thus, we can easily write by taking \([A]\{u\}\) as the vector function \(\left\{f(t,\{u\})\right\}\) in the sample initial value problem \(\ddot{u} = f(t, u)\). So,

\[
\left\{f(t,\{u\})\right\} = [A]\{u\}
\]

(26)

The Matlab program has been used to solve this problem and get the velocity distribution.

5. Numerical Results and Discussion

In this paper, numerical solution (Comparative Study) using a new technique is applied to study slip effect of unsteady MHD pulsatile flow through porous medium in an artery under the influence of periodic body acceleration using GDQM. A new technique gives a very good numerical solution for solving time dependent problems. The present approach of GDQM used the method of directly Substitutes the Boundary Conditions into the Governing Equations is referred to as (SBCGE); this method overcomes the drawbacks of the δ-technique in implementing the derivative conditions. The problem is reduced by using GDQM to a system of ODEs that is solved by the 4th order RKM. Numerical results of the problem is obtained and compared with available data in the literature and found that the present numerical schemes give better solutions.

A numerical code has been written to calculate the axial velocity according to Equation (23). In order to check our code and to discuss the stability and accuracy of the new technique, comparison the results with the exact solution [41], we run it for the parameters related to a realistic physical problem similar to [41]. Figure 1, Figure 2 for steady MHD flow through a porous medium with constant pressure gradient, for instance, for \(A_0 = 1, Ha = 1, k = 0.5, k_0 = 0.0, t = \infty\) and \(r = 0.5\), we obtain the axial velocity \(u = 0.12374654323755\), which equals (if we keep 15 digits after the decimal point) to the result of [41].

Also comparison the results of the new technique with [32] [39] [42]-[44]. Also comparison the results of the new technique with the analytical solution [45], we run it for the parameters related to a realistic physical problem
similar to [45], for unsteady MHD pulsatile flow through porous medium in an artery under the effect of body acceleration, for instance, for $\alpha = 3, A_\omega = 2, A_1 = 4, a_\omega = 3, b = 2, Ha = 1, k = 0.5, k_n = 0.0, t = 1$ and $r = 0.5$, we obtain the axial velocity $u = 0.60950$ (if we keep five digits after the decimal point), which compared with the analytical solution [45].

In this paper, Slip effects on the unsteady MHD pulsatile blood flow through porous medium in an artery under the influence of periodic body acceleration have been studied. Figures 2-10 show effects of slip condition on the axial velocity with time. Figures 2-4 show the relation between the axial velocity with time on the steady
MHD blood flow through a porous medium with constant pressure gradient, we show from the figures that the presence of slip condition delay the time that the axial velocity need to reaches the steady state, when \( k_n = 0.0 \), the axial velocity reaches to steady state at \( t = 0.45 \sec \), when \( k_n = 0.09 \), the axial velocity reaches to steady state at \( t = 0.55 \sec \). and when \( k_n = 0.2 \), The axial velocity reaches to steady state at \( t = 0.65 \sec \). Figures 5-7
show the relation between the axial velocity with time on the unsteady MHD blood flow through a porous medium, we show from the figures that the presence of slip condition let to increase the amplitude of velocity oscillation at the peak. Figures 8-10 show the relation between the axial velocity with time on the unsteady MHD pulsatile blood flow through a porous medium under the effect of body acceleration, we show from the figures
that the presence of slip condition let to increase the amplitude of velocity oscillation at the peak. Comparison between Figures 5-7 and Figures 8-10 to study the effect of body acceleration we note that the velocity profile in the presence of body acceleration make two peak down and one beak above and the magnitude of the velocity increase at the peak.

The axial velocity profile computed by using the velocity (23) for different values of Hartmann number $Ha$, Knudsen number $k_n$, Womersley parameter $\alpha$, frequency of body acceleration $b$, the parameter of porous medium $k$ and have been shown through Figures 11-20. Thereby, we can be controlling the process of flow. It is observed from Figures 11, Figure 12, that as the Hartmann number increases the axial velocity of the blood decreases. Figure 13, Figure 14 show the effect of the Knudsen number on the axial velocity distribution, we note that the axial velocity of the blood increases with increasing Knudsen number. Figure 15, Figure 16 the axial velocity of the blood increases with increasing the permeability parameter of porous medium. Figure 17, Figure 18 the axial velocity of the blood decreases with increasing the frequency of body acceleration. Figure 19, Figure 20 the axial velocity of the blood increases with increasing Womersley parameter.

6. Conclusions

In this paper, a GDQM is presented to obtain numerical solutions of Navier-Stokes equations. The problem is reduced to a system of ODEs that is solved by fourth order Runge-Kutta method. Numerical results of the unsteady pulsatile blood flow through porous medium in the presence of magnetic field with periodic body acceleration and slip condition through a rigid straight circular tube (artery) have been studied. It is of interest to note
that the axial velocity increases with increasing of the permeability parameter of porous medium, Womersley parameter and Knudsen number whereas it decreases with increasing the Hartmann number and frequency of body acceleration.

The present model gives a numerical solution of velocity distribution with pipe radius and time. It is of inter-
Figure 16. The effect of porosity number on velocity distribution with the pipe radius \[\alpha = 1, k_n = 0.02, A_0 = 1, A_1 = 1, a_0 = 1, b = 2, Ha = 1\].

Figure 17. The effect of frequency of body acceleration on velocity distribution with the pipe radius \[\alpha = 1, k_n = 0.02, A_0 = 1, A_1 = 1, a_0 = 1, Ha = 1, k = 0.5, t = 1\].

Figure 18. The effect of frequency of body acceleration on velocity distribution with time \[\alpha = 1, k_n = 0.02, A_0 = 1, A_1 = 1, a_0 = 1, Ha = 1, k = 0.5\].

It is noted that the result of the present model includes results of different mathematical models such as:

- The results of Eldesoky [32] have been recovered,
- The results of Eldesoky, Kamel, Reda, and Abumandour [39] have been recovered by taking Knudsen number \(k_n = 0.0\) (no slip condition),
The results of Megahed et al. [45], have been recovered by taking Knudsen number $kn = 0.0$ (no slip condition),
- the results of Kamel and El-Tawil [43] have been recovered by taking Knudsen number $kn = 0.0$ (no slip condition), the permeability of porous medium $k \rightarrow \infty$ without stochastic and nobody acceleration,
- The results of El-Shahed [44] have been recovered by taking Knudsen number $kn = 0.0$ (no slip condition) and Hartmann number $Ha = 0.0$ (no magnetic field),
- The results of Chaturani and Palanisamy [42] have been recovered by taking Knudsen number $kn = 0.0$ (no slip condition), the permeability of porous medium $k \rightarrow \infty$ and Hartmann number $Ha = 0.0$ (no magnetic field).

It is possible that a proper understanding of interactions of body acceleration with blood flow may lead to a therapeutic use of controlled body acceleration. It is therefore desirable to analyze the effects of different types of vibrations on different parts of the body. Such knowledge of body acceleration could be useful in the diagnosis and therapeutic treatment of some health problems (joint pain, vision loss, and vascular disorder), to better design of protective pads and machines.

By using an appropriate magnetic field it is possible to control blood pressure and also it is effective for conditions such as poor circulation, travel sickness, pain, headaches, muscle sprains, strains, and joint pains. The slip condition plays an important role in shear skin, spurt and hysteresis effects. The fluids that exhibit boundary slip have important technological applications such as in polishing valves of artificial heart and internal cavities.

Hoping that this investigation may have for further studies in the field of medical research, the application of magnetic field for the treatment of certain cardiovascular diseases, and also the results of this analysis can be
applied to the pathological situations of blood flow in coronary arteries when fatty plaques of cholesterol and artery clogging blood clots are formed in the lumen of the coronary artery. The study is useful for evaluating the role of porosity when the body is subjected to magnetic resonance imaging (MRI).
