Abstract

We analyze the spectral distribution of localisation in a 1D diagonally disordered chain of fragments each of which consist of \( m \) coupled two-level systems. The calculations performed by means of developed perturbation theory for joint statistics of advanced and retarded Green’s functions. We show that this distribution is rather inhomogeneous and reveals spectral regions of weakly localized states with sharp peaks of the localization degree in the centers of these regions.

Keywords: Anderson Localization, Spectral Distribution, Green’s Function, 1D Disordered Chain

1. Introduction

The 1D models were traditionally studied in the theory of solid state for obtaining qualitative data, which were then used to analyze more realistic 3D models. For example, the exactly solvable Kronig-Penny model, which demonstrates the most important qualitative properties of the translationally symmetric systems, such as the band type of the energy spectrum and possibility of the wavevector-based classification of states, provided a basis for the modern theory of crystalline media. As the second (and far from the last) example may serve the Ising model in the theory of phase transitions, in which the exact analysis of the 1D model has shown a decisive role of dimentionality of the system for observation of its critical behavior. These examples, pertaining to the time when the solid state physics was at the stage of accumulation of knowledge show that analysis of even abstract 1D models (which do not correspond to any real physical system) may give an important qualitative information.

Note that, at present, there are all grounds to believe that the 1D models appear to be also important in other respects. Up-to-date technologies of material production and experimental techniques make it possible to create and study objects (quantum superlattices, quantum wires, J-aggregates, optical waveguiding fibers, etc.) that can be described quantitatively using such models. Still, the heuristic significance of the 1D models can be considered, nowadays, as the most important.

Among models of the physics of disordered systems, which, at present is also at the stage of accumulation of information, the 1D models occupy a particularly important place. At this stage, a consistent mathematical analysis of even an abstract model, capable of giving reliable and non-trivial results, is of interest. As examples of such an analysis may serve publications [1-4].

As is known [5,6], an important property of the homogeneously disordered systems is the appearance of localized states in their single-particle spectrum. Since these states play a decisive role in calculations of the charge transfer in disordered systems, any information about them is considered to be valuable. For getting information of this kind, in [7], a consistent perturbation theory for joint statistics of the advanced and retarded Green’s functions was proposed. This theory allows one to calculate distribution of the degree of localization of states (in the sense of the Anderson criterion [5,6]) as a function of their energy (called, hereafter, spectral dependence of the degree of localization). The calculation presented in [7] refers to the classical case of a disordered chain with a simplest structural unit, namely, a two-level system. The goal of this paper is, first, to generalize the method proposed in [7] to the case of a disordered chain with a more complicated structural unit—a segment comprised of \( m \) coupled two-level systems, and, second, to calculate spectral dependence of the degree of localization in such a system. The main quantitative result of the paper is derivation of an analytical
formula for the above degree of localization. The formula thus derived shows that distribution of the degree of localization over the energy spectrum, for the model with \( m > 1 \), is essentially inhomogeneous and is characterized by appearance of \( m - 1 \) energy points in which the states are virtually delocalized. This result provides grounds for the following qualitative conclusion: Spectral distribution of the degree of localization, in the 1D systems, may be essentially inhomogeneous and may reveal strongly pronounced maxima and minima. This behavior of the degree of localization qualitatively differs from that for the case of \( m = 1 \) considered in [7].

The fact that such a model with \( m = 2 \) can exhibit unusual behavior was described in [8] where for a binary disordered chain of dimers the indications of delocalization were founded.

The above model with complex structural unit can also be used as a simplest one describing the correlated disorder with parameter \( m \) playing the role of correlation length. The optical properties of similar random system were studied in [9] and it was shown that so-called factor of optical amplification for such system display nonmonotonic dependence on correlation length. The important role of correlations was pointed out in [10] where the authors put forward arguments in favor of appearance of delocalized states in the case of spectral density of correlation function having the form

\[
\rho_{kk'} = \rho_0 \delta_{kk'} + \rho_1 \delta_{k+1,k'} + \rho_2 \delta_{k-1,k'}, \quad k, k' = 1, \ldots, N
\]

The quantity \( \rho_0 \) is known to be crucial in the theory of Anderson localization [5-7], according to which the nonzero \( \rho_0 \) indicates presence of localized eigenfunctions (in the sense of Anderson criterion) among those of Hamiltonian (1). To judge about the degree of localization of the eigenvectors of (1) in the spectral range \( [0, U - dU] \), we have introduced, in [7], the participation function \( W(U) \), defined by the relationship

\[
W(U) = \frac{1}{N} \sum_{k=1}^{N} |\phi_k|^2
\]

Obviously, \( W(U) \) is connected with the squared module of the frequency spectrum of vibrations of the edge oscillator.

2. Formulation of the Problem, and the Main Results

Let us pass to quantitative formulation of the problem. Consider a 1D chain of two-level atoms consisted of fragments with the length \( m \). We assume that splittings of all the atoms within a fragment are the same, while the disorder is provided by randomness of the splittings from fragment to fragment. The splittings corresponding to different fragments will be considered as independent random quantities with a known distribution function \( P(\epsilon) \). Such a system differs from the standard one by that the structural unit is a fragment of \( m \) coupled two-level systems, rather than a single two-level system. Thus, the Hamiltonian matrix \( H \), in the studied model, will have a usual form

\[
H_{\epsilon,\epsilon'} = \delta_{\epsilon,\epsilon'} \epsilon_{\epsilon} + \delta_{\epsilon,\epsilon'\pm 1} \epsilon_{\epsilon'\pm 1}, \quad \epsilon, \epsilon' = 1, \ldots, N
\]

where the diagonal elements \( \epsilon_{\epsilon} \) correspond to the fragments described above. If, for example, \( m = 2 \), then \( \epsilon_1 = \epsilon_2 \neq \epsilon_3 = \epsilon_4 \neq \epsilon_5 = \epsilon_6 \neq \cdots \) and the elements \( \epsilon_1, \epsilon_2, \epsilon_3, \cdots \) are the random independent quantities with the distribution function \( P(\epsilon) \). The off-diagonal elements equal to unity determine the energy scale. In what follows, we will imply the thermodynamic limit \( N \rightarrow \infty \).

For this model, we consider the following problem. Let the edge atom is excited at \( t = 0 \), and we have to find the probability \( D \) that this atom remains in the excited state at \( t \rightarrow \infty \). Mathematically, it means that the initial state of the system is described by the wave function (vector-column) \( \Psi^r(0) \) with the components \( \Psi^r_{\epsilon,0} = \delta_{\epsilon,0} \), and we have to find

\[
D = \left| \Psi^r(t \rightarrow \infty) \right|^2
\]

The quantity \( D \) is known to be crucial in the theory of Anderson localization [5-7], according to which the nonzero \( D \) indicates presence of localized eigenfunctions (in the sense of Anderson criterion) among those of Hamiltonian (1). To judge about the degree of localization of the eigenvectors of (1) in the spectral range \( [U, U - dU] \), we have introduced, in [7], the participation function \( W(U) \), defined by the relationship

\[
W(U) = \frac{1}{N} \sum_{k=1}^{N} |\phi_k|^2
\]

It was shown in [7] that, when all the states, within the interval \( [U, U + dU] \), are delocalized, then \( W(U) = 0 \). Otherwise, \( W(U) \) is nonzero. One may easily check, that the function \( W(U) \) has also the sense of average squared module of the frequency spectrum of oscillations of the wave function at the edge site).

\[\text{In the vibration-related problems, when the dynamic matrix has the form close to (1), the function } W(U) \text{ is connected with the squared module of the frequency spectrum of vibrations of the edge oscillator.}\]
oscillations do not decay, which corresponds to nonzero value of $W(U)$.

As was already mentioned, the physics of disordered systems is, at present, at the initial stage of its evolution, when testing theoretical results in a real experiment cannot look convincing. For this reason, as an especially important property of the discrete models described by the Hamiltonian of type (1), should be considered possibility of their simple numerical analysis. Fantastic capabilities of the contemporary computers allow one to diagonalize matrices of type (1) for a reasonable time and to observe, in such a numerical experiment, the quantities (2) and (3) at $N \sim 1000$ and more, checking, in this way, the appropriate theoretical predictions with a high degree of reliability. The main result of this paper is the following formulas for the participation function $W(U)$ and the quantity $D$, which are applicable to the 1D random chain with the complex structural unit described above:

$$W(U) = \frac{\Theta(2-|U|)}{\pi m \sqrt{4-U^2}} \cdot \sin^2 \left[ \text{marctg} \left( \frac{\sqrt{4-U^2}}{U} \right) \right] + O(\Delta^3), \quad (4)$$

$$D = \frac{\Delta^2 M^2}{2m} + O(\Delta^3)$$

Here, the quantity $\Delta$ is the parameter of the site energy distribution function, which we take in the form

$$P(x) = p(x/\Delta)/\Delta, \; p(x) > 0,$$

$$\int p(x) \, dx = 1, \; \int p(x) \, x \, dx = 0, \; \int p(x) \, x^2 \, dx = M_2$$

It follows from Equation (4) that, for the energies defined by the condition

$$\text{arctg} \left( \frac{\sqrt{4-E^2}}{E_n} \right) = \frac{\pi n}{m}, \; E_n = \pm 2 \sqrt{\left[ \frac{\pi n}{m} \right]^2 + 1}, \quad (5)$$

the participation function $W(E_n)$ vanishes to within the terms $\sim \Delta^3$, i.e., the states in these energy points appear to be, in the considered approximation, delocalized. This result looks strange because it is considered proven [5] that, in a 1D homogeneous random system, all the states are localized. In this connection, we performed analysis of the next term in expansion of the function $W(U)$ in powers of $\Delta$. The analysis has shown that this term diverges at $U = E_n$ (5). Due to this counter-directed behavior of contributions of different orders, Equation (4), at small disorder (i.e., at small $\Delta$), should work well at any energy except for small regions in the vicinity of $E_n$. In these points (where the correction $\sim \Delta^3$ (4) vanishes), narrow peaks of the participation function $W(U)$, corresponding to divergence of the next correction, should be observed. The numerical experiment described in the last section of the paper completely confirms this conclusion.

### 3. Green’s Function Statistics

It can be easily shown that the mean square of the wave function module at the edge site $\langle |\Psi_N(t)|^2 \rangle$ (which is connected with quantity (2) we are interested in by the relation $D = \langle |\Psi_N(x)|^2 \rangle$) can be calculated in the following way:

$$\langle |\Psi_N(t)|^2 \rangle = \lim_{t_1, t_2 \to \infty} \frac{1}{4\pi^2} \int dU_1 dU_2 \exp[i(U_1 - U_2)t] \cdot \langle \gamma(U_1 - iV) \gamma(U_2 + iV) \rangle$$

where $\gamma(\Omega)$ is the edge Green’s function (EGF) for Hamiltonian (1):

$$\gamma(\Omega) = \sum_\Delta \frac{|\Psi_\Delta|^2}{\Omega - E_\Delta} \quad (7)$$

To calculate the mean value of the product of two Green’s functions entering Equation (6) at different complex energies $\Omega_1 = U_1 - iV_1$ and $\Omega_2 = U_2 + iV_2$, one has to know their joint distribution function (statistics) $\rho(\alpha, \beta, \alpha_2, \beta_2)$, $\rho(\alpha, \beta, \alpha_2, \beta_2) \, d\alpha \, d\beta \, d\alpha_2 \, d\beta_2$ is the probability that $\text{Re} \gamma(\Omega_1) \in [\alpha, \alpha + d\alpha]$ and $\text{Im} \gamma(\Omega_1) \in [\beta, \beta + d\beta]$, $i = 1, 2$). We will usually write down the function $\rho$ as a function of two complex variables $z_i = \alpha_i + i\beta_i$, $i = 1, 2$: $\rho(\alpha, \beta, \alpha_2, \beta_2) = \rho(z, z_2)$. We derive equation for this function using the method of [7,11].

Consider the chain described in Introduction, whose structural unit is a fragment consisting of $m$ two-level systems. Let $N$ be the number of the edge two-level system of the edge fragment and $\gamma_N$—the EGF of such a chain. If we add to this chain one more fragment consisted of $m$ sites with the splitting $\epsilon$, then the EGF $\tilde{\gamma}$, corresponding to the edge site of this new chain can be expressed through $\gamma$:

$$\tilde{\gamma}(\Omega) = R^{-1}_{\Omega-\epsilon} (\gamma) \quad (8)$$

The explicit form of the function $R^{-1}_{\Omega-\epsilon} (\gamma)$ entering this equation, for an arbitrary $m$, will be given below, and now, we remind that, for the case $m = 1$,

$$R^{-1}_{\Omega-\epsilon} (\gamma) \big|_{m=1} = \frac{1}{[\Omega - \epsilon - \gamma]} \quad [5,7,11].$$

Relationship (8)
allows us to express statistics of the edge Green’s functions of the chain with the added fragment \( \hat{\rho}(x_1, y_1, x_2, y_2) \) through the function \( \rho(\alpha, \beta \alpha, \beta') \) of the initial chain as follows

\[
\hat{\rho}(x_1, y_1, x_2, y_2) = \int \frac{d\alpha d\beta \alpha d\beta' \alpha \rho(\alpha, \beta \alpha, \beta')}{\sqrt{\Delta_{12}(\alpha, \beta) \Delta_{21}(\alpha, \beta)}} \delta[x_1 - Re\Delta_{12}^{-1}(\alpha + i\beta)] \delta[y_1 - Im\Delta_{12}^{-1}(\alpha + i\beta)]
\]

(9)

It is clear that, in the thermodynamic limit \( N \to \infty \), \( \hat{\rho} \) should coincide with \( \rho \). By calculating the integrals for \( \delta \) -functions in (9), we obtain the following equation for the steady-state joint distribution function of EGF:

\[
\rho(\gamma_1, \gamma_2) = \int \frac{d\alpha d\beta \alpha d\beta' \alpha \rho(\alpha, \beta \alpha, \beta')}{\sqrt{\Delta_{12}(\alpha, \beta) \Delta_{21}(\alpha, \beta)}} \delta[x_1 - Re\Delta_{12}^{-1}(\alpha + i\beta)] \delta[y_1 - Im\Delta_{12}^{-1}(\alpha + i\beta)]
\]

(10)

In this equation, symbol \( R \) denotes transformation inverse to (8), and the joint statistics \( \rho \) is written as a function of two complex arguments.

The fact that the Green’s functions entering Equation (6) have vanishingly small imaginary parts of the energy arguments can be used to reduce the problem to analysis of the equation much simpler than (10) [7]. The average product of the two Green’s functions, entering Equation (6), can be written in the form of the sum of four terms:

\[
\langle \gamma U_i \gamma U_j \rangle = \int dx_1 dy_1 dx_2 dy_2 \rho(x_1, y_1, x_2, y_2) [x_1 x_2 - y_1 y_2 + i(x_1 y_2 + x_2 y_1)]
\]

(11)

It was shown in [7], that it suffices to calculate the term \( \langle x_1 y_2 \rangle \) and to multiply the result by 4. Using Equation (10), we can write the quantity \( \langle x_1 y_2 \rangle \), we are interested in, in the form

\[
\langle x_1 y_2 \rangle = \int \frac{d\alpha d\beta \alpha d\beta' \alpha \rho(\alpha, \beta \alpha, \beta')}{\sqrt{\Delta_{12}(\alpha, \beta) \Delta_{21}(\alpha, \beta)}} \delta[x_1 - Re\Delta_{12}^{-1}(\alpha + i\beta)] \delta[y_1 - Im\Delta_{12}^{-1}(\alpha + i\beta)]
\]

(12)

where the real functions \( u_{\Omega}(x, y) \) and \( v_{\Omega}(x, y) \) and the Jacobians entering Equations (10) and (12) are determined by the relations

\[
u_{\Omega}(x, y) + i\nu_{\Omega}(x, y) = R_{\Omega}(x + iy)
\]

(13)

\[
\frac{dR_{\Omega_{12}^{-1}}(\gamma_1)}{d\gamma_1} = \frac{\partial u_{\Omega_{12}^{-1}}}{\partial \gamma_1} \frac{\partial u_{\Omega_{12}^{-1}}}{\partial \gamma_2} + \left( \frac{\partial v_{\Omega_{12}^{-1}}}{\partial \gamma_1} \right)^2 + \left( \frac{\partial v_{\Omega_{12}^{-1}}}{\partial \gamma_2} \right)^2
\]

(14)

\[
\gamma_i = x_i + iy_i \quad (i = 1, 2). \text{ In Equation (14), we used the Cauchy-Riman relations. In integral (12), we change the variables:}
\]

\[
\tilde{x}_1 = u_{\Omega_{12}^{-1}}(x_1, y_1), \quad \tilde{y}_1 = v_{\Omega_{12}^{-1}}(x_1, y_1), \quad \tilde{x}_2 = u_{\Omega_{21}^{-1}}(x_2, y_2), \quad \tilde{y}_2 = v_{\Omega_{21}^{-1}}(x_2, y_2)
\]

(15)

Since Jacobians of these transforms coincide with (14), for \( \langle x_1 y_2 \rangle \) we have:

\[
\langle x_1 y_2 \rangle = \int \frac{d\alpha d\beta \alpha d\beta' \alpha \rho(\alpha, \beta \alpha, \beta')}{\sqrt{\Delta_{12}(\alpha, \beta) \Delta_{21}(\alpha, \beta)}} \delta[x_1 - Re\Delta_{12}^{-1}(\alpha + i\beta)] \delta[y_1 - Im\Delta_{12}^{-1}(\alpha + i\beta)]
\]

(16)

with the form of \( x_1(\tilde{x}_1, \tilde{y}_1) \) and \( y_2(\tilde{x}_2, \tilde{y}_2) \) being determined by the function \( R_{\Omega_{12}^{-1}}(\gamma) \) (8):

\[
x_1 = Re\frac{R_{\Omega_{12}^{-1}}(\tilde{x}_1 + i\tilde{y}_1)}{R_{\Omega_{12}^{-1}}(\tilde{x}_1 + i\tilde{y}_1)} \quad \text{and} \quad y_2 = Im\frac{R_{\Omega_{12}^{-1}}(\tilde{x}_2 + i\tilde{y}_2)}{R_{\Omega_{12}^{-1}}(\tilde{x}_2 + i\tilde{y}_2)}
\]

(17)

As shown in [7], to calculate \( \langle x_1 y_2 \rangle \) at vanishingly small imaginary parts of the energy arguments (i.e., at \( V_i \to +0 \)), we may replace, in (16), \( \rho \) by its limiting value \( \rho_0 \), which corresponds to pure real energies \( \Omega_i \to U_i \) (i = 1, 2), whereas in (17), one has to take into account imaginary parts \( V_i \) of the energy arguments (taking advantage, when possible, of their smallness). The reasoning similar to that presented in [7] shows that the function \( \rho_0 \) can be represented in the form:

\[
\rho_0(x_1, y_1, x_2, y_2) \equiv \rho(x_1, y_1, x_2, y_2)_{|_{\Omega_{i2}^{-1}=\epsilon_{12}}}
\]

(18)

where the function \( \sigma_{\Omega_{i2}^{-1}}(x_1, x_2) \) controls statistics of the real Green’s functions and meets the equation that is much simpler than (10):

\[
\sigma_{\Omega_{i2}^{-1}}(x_1, x_2) = \int \frac{d\alpha d\beta \alpha d\beta' \alpha \rho(\alpha, \beta \alpha, \beta')}{\sqrt{\Delta_{12}(\alpha, \beta) \Delta_{21}(\alpha, \beta)}} \delta[x_1 - Re\Delta_{12}^{-1}(\alpha + i\beta)] \delta[y_1 - Im\Delta_{12}^{-1}(\alpha + i\beta)]
\]

(19)
Thus, in Equations (16) and (17), we may set $\bar{y}_{1,2} = 0$, since Equation (18) for $\rho_0$ contains the relevant $\delta$-functions. Since transformation (8) for real $\gamma$ and $\Omega$ gives real result, we may write, for $x_i$:

$$x_i = R_{\Omega i}^{-1}(\bar{x}_i)$$

(20)

An essentially different situation takes place for the quantity $y_2$ from Equation (17), which, with allowance for the above remarks, has the form

$$y_2 = \text{Im} R_{\Omega i}^{-1}(\bar{y}_2)$$

The imaginary part of this expression, in the general case, tends to zero, because the transform $R_{\Omega i}^{-1}$ is real at $V \rightarrow 0$. The exceptions are peculiarities of the transform $R_{\Omega i}^{-1}$, i.e., the values of its argument $x_0$ at which $R_{\Omega i}^{-1}(x_0) \rightarrow \infty$. At this stage of the calculation, we need the explicit form of the transformation $R_{\Omega i}^{-1}(x)$:

$$R_{\Omega i}^{-1}(x) = \frac{\sin (m \phi) - \sin [\frac{(m-1)\phi}{m+1} x]}{\sin [(m+1)\phi] - \sin (m \phi) x} = a_\Omega + b_\Omega x$$

(21)

where

$$\phi = -\text{arctg} \left[ \frac{\sqrt{4 - \Omega^2}}{\Omega} \right] - \pi \Theta(-\Omega)$$

The peculiarity $z_0 = -c_\Omega / g_\Omega = a_0 + ib_0$ of the function $R_{\Omega i}^{-1}(z)$ corresponds to zero denominator in (21), and, in the limit $\text{Im} \Omega \rightarrow 0$, we are interested in, its imaginary part tends to zero. Bearing this in mind and using the same reasoning as in Footnote, one may make sure that Equation (17), for $y_2$, can be rewritten in the form:

$$y_2|_{V \rightarrow 0} = \lim_{t \rightarrow 0} \text{Im} \frac{R_{\Omega i}^{-1}(\bar{y}_2)}{g_\Omega}$$

$$= \pi \frac{a_\Omega g_\Omega - b_\Omega c_\Omega}{g_\Omega} \delta(\bar{x}_z + c_\Omega)$$

(22)

$$U = U_z - \varepsilon$$

From Equations (20) and (21), we obtain the following expression for $x_1$:

$$x_1|_{V \rightarrow 0} = \frac{a_\Omega + b_\Omega x}{c_\Omega + g_\Omega x}, \quad U = U_1 - \varepsilon$$

(23)

By replacing, in (16),

$$\rho_{\Omega i}(x, y) \rightarrow \sigma_{\Omega i}(x, y) \delta(y)$$

(Equation (18)) and by substituting in to it Equations (22) and (23) for $y_2$ and $x_1$, we obtain

$$\langle x_i y_2 \rangle = \pi \int_0^1 \frac{dx P(x)}{g_\Omega} \sigma_{\Omega i}(x, y)$$

(24)

To further simplify this expression, we introduce a new variable:

$$z = \frac{a_\Omega + b_\Omega x}{c_\Omega + g_\Omega x}$$

Then

$$x = R_{\Omega i}^{-1}(z)dz = \frac{dR_{\Omega i}^{-1}(z)}{dz}$$

(25)

Then, Equation (24) can be transformed into the form

$$\langle x_i y_2 \rangle = -\pi \text{Im} P(z) \frac{dR_{\Omega i}^{-1}(z)}{dz} \sigma_{\Omega i}(z) \left( R_{\Omega i}^{-1}(z) \right) = -\pi \text{Im} P(z) \frac{dR_{\Omega i}^{-1}(z)}{dz} \sigma_{\Omega i}(z)$$

(26)

It follows from Equation (19) that

$$\lim_{a \rightarrow \infty} a \sigma_{\Omega i}(z, a)$$

(27)

From (21), one can easily obtain

$$R_{\Omega i}(z) = \frac{a_{\Omega i} - c_{\Omega i} z}{g_{\Omega i} z - b_{\Omega i}}, \quad \frac{dR_{\Omega i}(z)}{dz} = \frac{b_{\Omega i} c_{\Omega i} - a_{\Omega i} g_{\Omega i}}{[g_{\Omega i} z - b_{\Omega i}]^2}$$

(28)

and calculate the limits entering Equation (27)

$$\lim_{a \rightarrow \infty} a \sigma_{\Omega i}(z, a)$$

(29)

By comparing (27) and (26), we eventually have

$$\langle x_i y_2 \rangle = \pi \int_0^1 \sigma_{\Omega i}(x, a) x\ dx$$

(30)

This can be clarified by the following example. Let, e.g.,

$$R^1(x, y) = \frac{1}{2} / (x + i y)$$

where, in the general case, $\Omega = U + i V$ and $x = x + iy$. For real $\Omega$ and $\gamma (V = y = 0)$, this transformation is real and has a singularity at $x = -U$. If $V \neq 0$, then an imaginary part, located in this singularity (at small $V$), arises: Im $\Omega^* = (-U - x) + V$. In our case, the transformation $R_{\Omega i}(\gamma)$ is more complicated, but its imaginary part arises like in this simple example.
4. Calculating the \( <x_Uy_2> \) Contribution

Let us change variables in Equation (6):

\[
\omega = U_2 - U_1, U = U_1 \, . \quad \text{Then, with allowance for the remark given after Equation (11) and Equation (30), we may write the following expression for the quantity } \, D : \]

\[
D = \left\{ \left| \mathcal{W}_N (t \rightarrow \infty) \right|^2 \right\} _{\omega \rightarrow 0} \quad \text{and is zero},
\]

\[
= \frac{i}{\pi} \lim_{\omega \rightarrow 0} \int e^{i \omega t} (x_1, y_2) d \omega dx U
\]

(31)

Note that, as was shown in [7], the participation function \( W(U) \) can be obtained from (31) by omitting in it the integration over \( U \)

\[
W(U) = \frac{i}{\pi} \lim_{\omega \rightarrow 0} \int e^{i \omega t} \sigma_{L \rightarrow \omega} (x, a) dx d \omega \omega \quad \text{(32)}
\]

Following methodology of [7], we can represent the distribution function of the site energies \( P(\varepsilon) \) in the form

\[
P(\varepsilon) = \frac{1}{\Delta} P \left( \frac{\varepsilon}{\Delta} \right), \quad p(x) > 0, p(x) dx = 1, \quad \int p(x) x^n dx = M_n M_1 = 0 \quad \text{(33)}
\]

In the case of an ordered chain, \( \Delta \rightarrow 0 \) and, as a result, \( D = W(U) = 0 \). The perturbative approach to solution of the equation similar to Equation (19), proposed in [7], represents expantion in powers of \( \Delta \), with the first nonzero correction being of the order of \( \Delta^2 \). It was also shown in [7] that, for calculation of the quantities \( D \) and \( W(U) \), it suffices to have only the singular in \( \omega \) part of solution of the equation for joint statistics of the Green’s functions (Equation (19)), with the singularity being of the pole type. Therefore, if we denote this singular part by the symbol “sing,” then we may present it in the form

\[
sing \sigma_{L \rightarrow \omega} (x, y_2) = \frac{\Delta^2}{\omega} F_U (x, y_2) + O(\Delta^3) \quad \text{(34)}
\]

Using Equation (30), we obtain the following formula for the sought function \( W(U) \):

\[
W(U) = -\Delta^2 \lim_{\omega \rightarrow 0} \left\{ \frac{F_U}{\omega} (x, a) dx \right\} + O(\Delta^3) \quad \text{(35)}
\]

In the next section, we describe the perturbation theory for solving Equation (19) and derive explicit expression for the function \( F_U (x, y_2) \).

5. Perturbative Approach to Equation (19)

Assuming that the parameter \( \Delta \) is small, we can present the sought function \( \sigma_{L \rightarrow \omega} (x, y_2) \) in the form of a power series in \( \Delta \)

\[
\sigma_{L \rightarrow \omega} (x, y_2) = \sum_{n=0}^{\infty} Q_n (x_1, x_2) \Delta^n
\]

(36)

Let us expand the function

\[
\sigma_{L \rightarrow \omega} \left[ R_{U \rightarrow \omega} (x_1), R_{U \rightarrow \omega} (x_2) \right] \frac{dR_{U \rightarrow \omega} (x_1)}{dx_1} \frac{dR_{U \rightarrow \omega} (x_2)}{dx_2}
\]

under the integral sign, in the right-hand side of Equation (19), into power series in \( \varepsilon \). Then, Equation (19) yields:

\[
\sum_{n=0}^{\infty} Q_n (x_1, x_2) \Delta^n
\]

(37)

By equating the coefficients of the same powers of \( \Delta \) in the left- and right-hand sides of (37), we obtain the recurrent relation for the functions \( Q_n \):

\[
\Delta^0 : Q_0 (x_1, x_2) = Q_0 \left[ R_{U \rightarrow \omega} (x_1), R_{U \rightarrow \omega} (x_2) \right] = 0
\]

(38)

Since the first moment of the function \( P(\varepsilon) \) is zero, we have \( Q_1 (x_1, x_2) = 0 \).

\[
\Delta^2 : Q_2 (x_1, x_2) = Q_2 \left[ R_{U \rightarrow \omega} (x_1), R_{U \rightarrow \omega} (x_2) \right] = 0
\]

(39)

Now, we define the linear operator \( H^m \) that acts upon an arbitrary function \( f(x) \) as follows:

\[
H^m f(x) = \frac{dR_{U \rightarrow \omega}}{dx} f \left[ R_{U \rightarrow \omega} (x) \right] \quad \text{(40)}
\]

Here, \( R_{U \rightarrow \omega} (x) \) is the transformation inverse to (21). In [12], there has been solved the spectral problem for the operator \( H^m f(x) = f(U - 1/x) \). It was shown that, at \( |U| < 2 \), its eigenvalues \( \lambda_n \) and eigenfunctions \( \sigma_{U \rightarrow \omega}^n (x) \) are given by the expressions:

\[
\lambda_n = \left( U + i \sqrt{4 - U^2} \right)^n \quad \text{and} \quad \lambda_n = \left( U - i \sqrt{4 - U^2} \right)^n \quad \text{(41)}
\]
where
\[ G_U(x) = \frac{R_U - x}{R_U - x}, R_U = \frac{U + i\sqrt{4-U^2}}{2}, R'_U = \frac{U - i\sqrt{4-U^2}}{2} \]
and Lorentzian  \( L_U(x) \) is defined as:
\[ L_U(x) = \frac{\sqrt{4-U^2}}{2\pi} \frac{1}{x^2 - Ux + 1} = \frac{1}{2\pi i} \left[ \frac{1}{x - R_U} - \frac{1}{x - R'_U} \right] \]
(42)

Remind [12] that an arbitrary function \( f(x) \) may be presented in the form of the series
\[ f(x) = \sum_{n=-\infty}^{\infty} A_n \sigma^n_U(x) \]
(43)
One can easily make sure that the functions \( \sigma^n_U(x) \) are also the eigenfunctions for the operator \( H^m \) (40), and the eigenvalues are given by \( m \)-th power of eigenvalues (41): \( H^m \sigma^n_U(x) = \lambda^n_m \sigma^n_U(x) \). The functional operator \( H^m \) enters Equations (38) and (39).

Taking into account its properties described above, we can immediately write the expression for \( Q_d(x_1,x_2) \):
\[ Q_d(x_1,x_2) = L_U(x_1) L_U(x_2) \]
(44)

To solve the functional Equation (39), let us write the sought function \( Q_d(x_1,x_2) \) in the form of expansion over eigenfunctions of operator (40):
\[ Q_d(x_1,x_2) = \sum_{|\alpha|,|\beta|>0} C_{\alpha \beta} \sigma_\alpha U(x_1) \sigma_\beta U(x_2) \]
(45)

By substituting this series into the left-hand side of Equation (39) and expanding its right-hand side using (43), we obtain, for the coefficients \( C_{\alpha \beta} \) (45), the following formulas:
\[ C_{\alpha \beta} = \frac{1}{1 - \lambda^n_U(U_1) \lambda^n_U(U_2)} \frac{M_2}{2} \frac{\partial^2}{\partial \varepsilon^2} \left[ J_n(U,\varepsilon) J_1(U,\varepsilon) \right] \mid_{\varepsilon=0} \]
(46)
where \( J_n(U,\varepsilon) \) are given by
\[ J_n(U,\varepsilon) = \frac{L_U(R_{U-x})(R_{U-x})}{G^n_U(x)} \] 
\[ = \int_{\varepsilon} L_U(z) G^n_U(R_{U-x}(z)) dz = J_n^*(U,\varepsilon) \]
(47)

To expand the right-hand side of (39), we used Equation (44) for the function \( Q_d(x_1,x_2) \).

As was said above, we are interested only in the part of \( Q_d(x_1,x_2) \) singular in \( \omega = U_2 - U_1 \). To extract this part, we have to retain in Equation (45) only the terms with \( n = -l \) [7], because only for these terms the denominator \( 1 - \lambda^n_U(U_1) \lambda^n_U(U_2) \), in Equation (46), vanishes at \( \omega = 0 \). The calculations identical to those performed in [7] lead to the following expression for the function \( F_{U}(x_1,x_2) \) entering Equation (34):
\[ F_U(x_1,x_2) = \frac{-iM_2}{4m} \sqrt{4-U^2} \sum_{n>0} \sigma^n_U(x_1) \sigma^n_U(x_2) \]
(48)

Here are the explicit expressions for integrals (47):
\[ J_n(U,\varepsilon) = 1, \]
\[ J_n(U,\varepsilon) = G^n_U(R_{U-x}(R_0)) = [J_1(U,\varepsilon)]^n \]
(49)

These expressions are obtained by integrating (47) over residues. When calculating the derivatives entering (48), the quantity \( \varepsilon \) can be considered so small that the arrangement of the poles of the integrants with respect to the real axis does not depend on \( \varepsilon \).

Using properties of the function \( G_U(x) \) presented in [12], we can obtain the following relationship
\[ \frac{1}{G^n_U(R_{U-x}(z))} = \lambda^n_m \frac{1}{G^n_U(z)} = \lambda^n_m \left( \frac{R_{U-x} - z}{R_{U} - z} \right) \]
(50)
which shows that \( J_n(U,0) = 0 \) at \( n \neq 0 \) and that, in the general case, the expansion of \( G^{-1}_U(R_{U-x}(R_{U-x})) \) in powers of \( \varepsilon \) starts from the first power of \( \varepsilon \) and may be written in the form:
\[ G^{-1}_U(R_{U-x}(R_{U-x})) = J_1(U,\varepsilon) = K_1 \varepsilon + T_1 \varepsilon^2 + O(\varepsilon^3) \]
(51)

By substituting this expression into (49), we see that, in Equation (48), only the terms containing \( J_n(U,\varepsilon) \) survive, for which the second derivative of their module squared is nonzero at \( \varepsilon = 0 \). Thus, Equation (48) for the function \( F_U(x_1,x_2) \) may be transformed to the form:
\[ F_U(x_1,x_2) = \frac{-iM_2}{2m} \sqrt{4-U^2} \left[ K_1 \right]^2 \]
(52)

The direct algebraic calculation with the use of explicit expressions (41) and (21) for the function \( G_U(x) \) and transformation \( R^{-1}_U(x) \), respectively, shows that
\[ K_1 = \frac{R^{n+1}_U}{4-U^2} \left[ (R^1_U)^n - R^{n-1}_U \right] K^2_1 = 4 \left( \frac{\sin m\phi}{4-U^2} \right)^2 \]
(53)

Finally, using the expressions for the moments and limiting values of the function \( \sigma^n_U(x) \), presented in [7]
\[ \int \sigma^n_U(x) \ dx = \frac{i}{2} \frac{n}{|n|} \sqrt{4-U^2}, \lim_{a \to \infty} \sigma^n_U(a) = \frac{\sqrt{4-U^2}}{2\pi} \]
(54)
with the aid of Equation (35), we obtain, for the participation function \( W(U) \) and the quantity \( D \), formula (4).

### 6. Delocalization Points

As was mentioned in Introduction, the appearance of the delocalization points (5) predicted in Equation (4) looks curious, taking into account the known assertion that all states in a 1D random system are localized [5]. The fact that the character of the states of Hamiltonian (1) (localized/delocalized), calculated in the second perturbation order, appears to be, in these energy points, the same as in the totally ordered system, indicates that, for studying the states with energies (5), one has to analyze statistics of Green’s functions to within the terms of the order higher than \( \Delta^2 \). Complete analysis of this kind is rather cumbersome and lies outside the scope of this paper. Still, with the aid of reasoning presented below, it is exactly in the vicinity of the points \( E_a(5) \) where the behavior of the participation function \( W(U) \) can be predicted.

Assume that the odd moments of the site energy distribution function \( P(\varepsilon) \) (33) are zeros \( (M_{2n+1} = 0) \) and consider the fourth-order correction \( Q_4 \) in expansion (36) of the joint statistics of Green’s functions. The functional equation for this correction is derived in the form as Equation (39) for \( Q_2 \) and has the form:

\[
\Delta^4 : Q_4(x_1, x_2) - Q_4\left[R_{U_{1,2}}(x_1) R_{U_{1,2}}(x_2)\right] \frac{dR_{U_{1,2}}(x_1)}{dx_1} \frac{dR_{U_{1,2}}(x_2)}{dx_2} = M_2 \frac{\partial^2}{\partial \xi^2} \left[ Q_o \left[R_{U_{1,2}}(x_1) R_{U_{1,2}}(x_2)\right] \frac{dR_{U_{1,2}}(x_1)}{dx_1} \right] \frac{dR_{U_{1,2}}(x_2)}{dx_2} \bigg|_{\xi=0} \]

(55)

The right-hand side of this equation is a sum of contributions, so that, if dependence of any of them on energy arguments \( U_{1,2} \) has a peculiarity, then such a peculiarity will be displayed by the function \( Q_4(x_1, x_2) \). We will now show that some terms of series (45), for function \( Q_4(x_1, x_2) \), diverge at the values of their energy arguments \( U_{1,2} \) equal to \( E_a(5) \).

Using Equations (46), (49), and (51), one can make sure that, among the coefficients \( C_{n_1} \) (46), nonzero are only \( C_{1,1} = C_{1,-1}, C_{1,-1} = C_{1,1}, \ C_{1,0} = C_{1,0}, C_{0,1} = C_{0,1}, \ C_{2,0}, C_{0,2} \). Let us present expression, e.g., for \( C_{1,0} \). Equation (46) yields:

\[
C_{1,0} = \frac{M_2 T_{U_{1,2}}}{1 - \lambda^m(U_1) \lambda^m(U_2)}
\]

(56)

where \( T_{U_{1,2}} \) is determined by Equation (51). It can be easily shown that \( \lambda^m(E_a)^m = 1 \) (41) and \( T_{U_{1,2}} \neq 0 \) (51).

It is this fact that gives rise to the above divergence of \( Q_4(x_1, x_2) \) at \( U_{1,2} = E_a(5) \), which, in turn, leads to divergence of the correction \( \Delta^4 \) to the participation function \( W(U) \). The terms \( Q_4(x_1, x_2) \) of expansion (45) proportional to \( C_{1,0}, C_{0,1} \) and \( C_{0,1} \) also diverge at \( U_{1,2} = E_a(5) \), with no compensation for the divergence.

Spectral behavior of other terms of the expansion at \( U_{1,2} = E_a(5) \) is essentially different. For instance, the coefficient \( C_{1,1} \) defined by the relationship

\[
C_{1,1} = \frac{K_{U_{1,2}}}{1 - \lambda^m(U_1) \lambda^m(U_2)}
\]

(57)

tends to zero at \( U_{1,2} = E_a(5) \) because the product \( K_{U_{1,2}} \) tends to zero faster than \( 1 - \lambda^m(U_1) \lambda^m(U_2) \).

Appearance of divergence is also possible in the points other than \( E_a \) Equation (5), where the corresponding peculiarities of the function \( W(U) \) are, however, not so noticeable, because the function \( W(U) \) calculated in the second order in \( \Delta \) is nonzero.

The divergence described above should look as a strong deviation of the participation function \( W(U) \), at \( U = E_a(5) \), from that described by Equation (4). The size of the spectral regions, in the vicinity of the points \( E_a(5) \), where the correction \( \Delta^4 \) begins to exceed the correction \( \Delta^2 \), calculated in this paper, will decrease with decreasing \( \Delta \). Since the correction \( \Delta^2 \) of the function \( W(U) \) turns to zero at \( U = E_a(5) \), the diverging corrections of higher orders should give rise to narrow (at small \( \Delta \) ) peaks in these spectral points. Quantitative description of the amplitude and shape of these peaks lies outside the scope of this paper.

### 7. Numerical Experiment

All the results obtained above refer to the case of an infinite 1D chain, and, therefore, in computer testing of these results, one has to employ matrices (1) of so large dimension that quantities (2) and (3) calculated for them, cease to depend on it. When choosing the matrix dimension for the numerical experiment, one may be governed by visual sense of Equation (4) which we consider below.
The qualitative picture of the excitation dynamics studied in this paper is that this excitation, being initially located at the edge site \( N \), remains localized near this site \( t \to \infty \). In this case, the appropriate wave function proves to be essentially nonzero only at some finite number of sites \( L \) in the vicinity of the edge site. The quantity \( D = \left\langle \Psi_N(t \to \infty) \right\rangle \) calculated in this paper and the normalization condition of the wave function provide opportunity to evaluate the number \( L \) as \( 1/D \) and to introduce the following natural definition for the mean localization radius \( \langle L \rangle \):

\[
\langle L \rangle = \frac{1}{D} = \frac{2m}{M_z \Delta^2}
\]  

(58)

It is evident that, in the numerical experiments, the matrix dimension \( N \) should substantially exceed \( \langle L \rangle \).

The participation function \( W(U) \) calculated in this paper, allows one to judge about spectral dependence of the localization radius. For, instance, if the function \( W(U) \), for some energy \( U \), is by a factor of \( k \) smaller than its mean value (equal to \( D/V_0 \), where \( V_0 \approx 4 \) is the width of the matrix (1) spectrum), then, we may say that the localization radius \( l(U) \) of the states with the energy \( U \) is by a factor of \( k \) larger than \( \langle L \rangle \). It means that the function \( W(U) \), obtained numerically, may strongly deviate from Equation (4) near the points of delocalization \( U = E_n \) (5), because the localization radius of the states with the energies close to \( E_n \) (5) substantially exceeds the mean one and may become greater than the matrix dimension \( N \) used in the numerical experiment.

The above reasoning shows the reasons why the smallest matrix dimension that can be used for the testing decreases with increasing degree of disorder \( \Delta \). On the other hand, evidently, it is possible to neglect the terms of the order higher than second, in Equation (4), only when \( D \ll 1 \), which is the case only at small \( \Delta \). For this reason, the degree of disorder \( \Delta \) and the matrix dimension \( N \), in the numerical testing, should, at least, meet the following condition:

\[
\frac{1}{N} \ll \frac{M_z \Delta^2}{2m} \ll 1
\]  

(59)

Our numerous computer experiments with matrices (1) of different dimension \( N \) and with the different degree of diagonal disorder \( \Delta \) support the above qualitative conclusions. To obtain statistics of site energies (33), in the numerical testing, we used the function

\[
\rho(x) = \Theta(x + 0.5) - \Theta(x - 0.5), M_z = 1/12
\]

Figure 1 shows spectral dependences of the function \( W(U)dU \) obtained numerically using Equation (3) (noisy plots) and the results of calculations using Equation (4) (smooth curves). The calculations were performed at \( \Delta = 0.5, dU = 1/50, m = 2 \) (Figure 1(a)) and \( m = 3 \) (Figure 1(b)). The matrix dimension was \( N = 4000 \), and averaging over 100 realization was made. One can see from Figures 1(a) and (b) that the numerical and theoretical dependences well agree with each other, with the points of delocalization (5) distinctly seen in both figures. The narrow peaks of the numerical plot in these points correspond to qualitative predictions made in the previous section.

Figure 1(c) shows the results of similar calculations for the disordered chain with \( m = 3 \). In this case, \( \langle L \rangle = 1152 \), and at \( N = 4000 \), condition (59) is satisfied relatively weak. One can see from Figure 1(c) that, in the spectral regions near the points of delocalization, where the localization radius of the states exceeds \( \langle L \rangle \) (58) and becomes comparable with \( N \), the discrepancy between the results of numerical experiments and theo-
retical curve is more noticeable than far away from these points. The calculations were performed with no fitting.

8. Conclusions

In this paper, we have analyzed spectral dependence of the degree of localization of the states in a 1D disordered chain with a complex structural unit in the form of a segment consisted of \( m \) two-level atoms. It is shown that distribution of the degree of localization, for such a model, qualitatively differs from that for the chain with a simple structural unit and is essentially inhomogeneous. This distribution is characterized by appearance of spectral regions in which the states are, to a considerable extent, delocalized, with exception of central points of these regions, where the degree of localization exhibits sharp peaks. The calculations are performed using the developed perturbative approach for the joint statistics of the advanced and retarded Green’s functions.

The work was supported by the Analytical Departmental Targeted Program “Development of Scientific Potential of Higher School” of 2009-2010 (project no. 2.1.1/1792).
