Abstract

In this paper we present a new method for solving the Stokes problem which is a constrained optimization method. The new method is simpler and requires less computation than the existing methods. In this method we transform the Stokes problem into a quadratic programming problem and by solving it, the velocity and the pressure are obtained.

Keywords: Galerkin Method, Neural Network Model, Quadratic Programming Problem, Stokes Problem

1. Introduction

Developing solutions to the Stokes equations has attracted many researchers because of its practical importance in the field of fluid mechanics. However, due to the nonlinear nature of Stokes equations the main stream of the solutions procedures are in fact numerical methods, which have been developed considerably in recent years because of the amazing advances in computing power and speed. However, very limited information is available in the form of analytical functions as the Stokes solutions especially, when the nonlinear terms remain in the governing equations.

Numerical approximation of incompressible flows presents a major difficulty, namely, the need to satisfy a compatibility condition between the discrete velocity and pressure spaces [1–3]. This condition which has been well known since the work of Babuska and Brezzi prevents, in particular, the use of equal order interpolation spaces for the two variables, which is the most attractive choice from a computational point of view.

To overcome this difficulty, stabilized finite element methods that circumvent the restrictive inf-sup condition have been developed for Stokes-like problems (see [4–6]). These residual-based methods represent one class of stabilized methods. They consist in modifying the standard Galerkin formulation by adding mesh-dependent terms, which are weighted residuals of the original differential equations. Although for properly chosen stabilization parameters these methods are well posed for all velocity and pressure pairs, numerical results reported by several researchers seem to indicate that these methods are sen-

sitive to the choice of the stabilization parameters. The local stabilization suggested in [6] has some advantages in this regard. Another class of stabilized methods has been derived using Galerkin methods enriched with bubble functions (see [7,8]). Alternative stabilization techniques based on a continuous penalty method have been proposed and analyzed in [9,10]. Nafa and Wathen analyzed pressure stabilized finite element methods for the solution of the generalized Stokes problem and investigated their stability and convergence properties. An important feature of the method is that the pressure gradient unknowns can be eliminated locally thus leading to a decoupled system of equations [11].

This paper is devoted to the Stokes system of differential equations. The Stokes problem describes the motion of an incompressible viscous fluid in a 2-dimensional domain:

$$\begin{aligned} -\nu \Delta \tilde{u} + \nabla p &= \tilde{f} && \text{in } \Omega \\ \operatorname{div} \tilde{u} &= 0 && \text{in } \Omega \\ \tilde{u} &= 0 && \text{on } \partial\Omega \end{aligned} \quad (1)$$

here $\tilde{u} = (u_1, u_2) : \Omega \rightarrow \mathbb{R}^2$ is the velocity field and $p : \Omega \rightarrow \mathbb{R}$ is the pressure. The first equation is the (linearized) momentum equation, while the second equation expresses the incompressibility constraint. Since we are assuming that the fluid is incompressible, no sources or sinks are present. The given external force field $\tilde{f} = (f_1, f_2)$ causes an acceleration of the flow. The pressure gradient gives rise to an additional force which prevents a change in the density. If (1) is satisfied by some functions $\tilde{u} \in [C^2(\Omega) \cap C^0(\Omega)]^2$ and $p \in C^1(\Omega)$

then we call \tilde{u} and p a classical solution of the Stokes problem. Note that (1) only determines the pressure p up to an additive constant, which is usually fixed by enforcing the normalization [1].

2. Mathematical Formulation and Analysis

We assume that $\tilde{f} \in (L^2(\Omega))^2$, and set

$$\tilde{V} := (H_0^1(\Omega))^2$$

$$Q = L_0^2(\Omega) = \left\{ q \in L^2(\Omega) : \int_{\Omega} q dx = 0 \right\}$$

$$V_{div} = \{\tilde{v} \in \tilde{V} : \operatorname{div} \tilde{v} = 0\}.$$

which are Hilbert spaces.

From the first equation of (1) and Green's formulae we obtain

$$a(\tilde{u}, \tilde{v}) + b(\tilde{v}, p) = \tilde{f}, \quad \forall \tilde{v} \in \tilde{V} \quad (2)$$

where

$$a(\tilde{u}, \tilde{v}) = \int_{\Omega} \nabla \tilde{u} \cdot \nabla \tilde{v} dx$$

$$b(\tilde{v}, p) = - \int_{\Omega} p \operatorname{div} \tilde{v} dx \quad \text{and}$$

$$(\tilde{f}, \tilde{v}) = \int_{\Omega} \tilde{f} \cdot \tilde{v} dx$$

Thus we have the variational form of the problem (1) as:

find $(\tilde{u}, p) \in \tilde{V} \times Q$ such that

$$\begin{aligned} a(\tilde{u}, \tilde{v}) + b(\tilde{v}, p) &= \tilde{f}, \quad \forall \tilde{v} \in \tilde{V} \\ b(\tilde{u}, q) &= 0 \quad \forall q \in Q \end{aligned} \quad (3)$$

In the following we state some conditions and theorems about the stability and convergence of the problem.

Definition: The bilinear forms

$$a(\cdot, \cdot) : \tilde{V} \times \tilde{V} \rightarrow R, \quad b(\cdot, \cdot) : \tilde{V} \times Q \rightarrow R$$

are called continuous if they satisfy

$$\begin{aligned} |a(\tilde{w}, \tilde{v})| &\leq \gamma \|\tilde{w}\|_{\tilde{V}} \|\tilde{v}\|_{\tilde{V}}, \\ |b(\tilde{w}, q)| &\leq \delta \|\tilde{w}\|_{\tilde{V}} \|q\|_Q, \quad \forall \tilde{w}, \tilde{v} \in \tilde{V}, q \in Q \end{aligned} \quad (4)$$

Also $a(\cdot, \cdot)$ is coercive if there exists a constant $\alpha > 0$ such that

$$a(\tilde{v}, \tilde{v}) \geq \alpha \|\tilde{v}\|_{\tilde{V}}^2 \quad \forall \tilde{v} \in \tilde{V}$$

We let

$$Z := \left\{ \tilde{v} \in \tilde{V} : b(\tilde{v}, q) = 0, \text{ for each } q \in Q \right\}$$

Theorem 1. (Existence and uniqueness) Assume that the bilinear form $a(\cdot, \cdot)$ satisfies (4) and coercive on Z , moreover, $b(\cdot, \cdot)$ satisfy (4) and that the following

compatibility (\inf_{\sup}) condition holds i.e., there exists $\beta > 0$ such that

$$\forall q \in Q \exists \tilde{v} \in \tilde{V}, \tilde{v} \neq 0 : b(\tilde{v}, q) \geq \beta \|\tilde{v}\|_{\tilde{V}} \|q\|_Q \quad (5)$$

Then for each $\tilde{f} \in (L^2(\Omega))^2$ there exists a unique solution $(\tilde{u}, p) \in \tilde{V} \times Q$ and

$$\begin{aligned} \|\tilde{u}\|_{\tilde{V}} &\leq \frac{1}{\alpha} \|\tilde{f}\|_0 \\ \|p\|_Q &\leq \frac{1}{\beta} \left(1 + \frac{\gamma}{\alpha}\right) \|\tilde{f}\|_0 \end{aligned} \quad (6)$$

For the proof of the above theorem see [12].

3. Discrete Mixed Formulation

We introduce two families of finite dimensional subspaces $\tilde{V}_h \subset \tilde{V}$ and $Q_h \subset Q$ depending on h . Then, we approximate (3) by the discrete problem: find $(\tilde{u}_h, p_h) \in \tilde{V}_h \times Q_h$ such that

$$\begin{aligned} a(\tilde{u}_h, \tilde{v}_h) + b(\tilde{v}_h, p_h) &= (\tilde{f}, \tilde{v}_h) \quad \forall \tilde{v}_h \in \tilde{V}_h \\ b(\tilde{u}_h, q_h) &= 0 \quad \forall q_h \in Q_h \end{aligned} \quad (7)$$

Similar to Z we let

$$Z_h := \left\{ \tilde{v}_h \in \tilde{V}_h : b(\tilde{v}_h, q_h) = 0, \text{ for each } q_h \in Q_h \right\}$$

This is the space of discretely divergence-free functions associated with finite dimensional spaces.

Theorem 2. (Existence and uniqueness) Assume that bilinear forms $a(\cdot, \cdot)$ and $b(\cdot, \cdot)$ are continuous. The existence and uniqueness of solution to the problem (3) follows from the coercivity of $a(\cdot, \cdot)$ on \tilde{V} and from discrete inf-sup condition. These two conditions are defined as follows:

There exists a constant $\alpha_h, \beta_h > 0$ such that

$$a(\tilde{v}_h, \tilde{v}_h) \geq \alpha_h \|\tilde{v}_h\|_{\tilde{V}}^2 \quad \forall \tilde{v}_h \in Z_h \quad (8)$$

$$\begin{aligned} \forall q_h \in Q_h \exists \tilde{v}_h \in \tilde{V}_h, \tilde{v}_h \neq 0 : \\ b(\tilde{v}_h, q_h) \geq \beta_h \|\tilde{v}_h\|_{\tilde{V}} \|q_h\|_Q \end{aligned} \quad (9)$$

Then for each $\tilde{f} \in (L^2(\Omega))^2$, there exists a unique solution $(\tilde{u}_h, p_h) \in \tilde{V}_h \times Q_h$ to (7) which satisfies

$$\|\tilde{u}_h\|_{\tilde{V}} \leq \frac{1}{\alpha_h} \|\tilde{f}\|_0$$

$$\|p_h\|_Q \leq \frac{1}{\beta_h} \left(1 + \frac{\gamma}{\alpha_h}\right) \|\tilde{f}\|_0$$

These estimates state that the solution is stable if β is independent of h . When the latter condition is not true,

or even worse, (5) doesn't hold, the approximation (7) is said to be unstable.

Theorem 3. (Convergence) Let the assumptions of Theorems (3) and (4) be satisfied. Then the solutions (\tilde{u}, p) and (\tilde{u}_h, p_h) to (3) and (7), respectively, satisfy the following error estimates

$$\begin{aligned} \|\tilde{u} - \tilde{u}_h\|_V &\leq (1 + \frac{\gamma}{\alpha_h}) \inf_{\tilde{v}_h^* \in Z_h} \|\tilde{u} - \tilde{v}_h^*\|_V + \frac{\delta}{\alpha_h} \inf_{q_h \in Q_h} \|p - q_h\|_Q \\ \|\tilde{p} - p_h\|_V &\leq \frac{\gamma}{\beta_h} (1 + \frac{\gamma}{\alpha_h}) \inf_{\tilde{v}_h^* \in Z_h} \|\tilde{u} - \tilde{v}_h^*\|_V + \\ &(1 + \frac{\delta}{\alpha_h} + \frac{\delta\gamma}{\alpha_h \beta_h}) \inf_{q_h \in Q_h} \|p - q_h\|_Q \end{aligned} \quad (10)$$

Moreover, the following estimate holds

$$\inf_{\tilde{v}_h^* \in Z_h} \|\tilde{u} - \tilde{v}_h^*\|_{\tilde{V}} \leq (1 + \frac{\delta}{\beta_h}) \inf_{\tilde{v}_h \in \tilde{V}_h} \|\tilde{u} - \tilde{u}_h\|_{\tilde{V}} \quad (11)$$

From (10) and (11) it follows that the convergence is optimal, provided that (8) and (9) hold with constants independent of h [12,13].

Using basis functions for V_h and Q_h , the problem (7) leads to the following system of linear equations:

$$\begin{bmatrix} A & B \\ B^T & 0 \end{bmatrix} \begin{bmatrix} U \\ P \end{bmatrix} = \begin{bmatrix} F \\ 0 \end{bmatrix} \quad (12)$$

where A is a symmetric positive definite matrix. It can be shown that the discrete inf-sup condition is satisfied or this system has a unique solution if and only if $\text{Ker}B = 0$ [1,12,13]. If $\text{Ker}B \neq 0$, then the coefficient matrix in (12) is singular, and the system has infinitely many solutions. In this case, for solving the system (12), we can use one of the iterative methods or the penalty method.

In this paper, we assume $\text{Ker}B \neq 0$. We introduce the quadratic programming method for solving the Stokes problem.

4. Illustration of the Method

In this section we present an optimization method for solving the problem (3).

Consider the following problem:

$$\begin{aligned} &\text{Minimize} \|\text{div} \tilde{u}\|_{L^2(\Omega)}^2 \\ &\text{subject to} \\ &a(\tilde{u}, \tilde{v}) + b(\tilde{v}, p) = (\tilde{f}, \tilde{v}), \quad \forall \tilde{v} \in \tilde{V} \\ &\int p dx = 0 \end{aligned} \quad (13)$$

The following theorem shows the relation of the solutions of (3) and (13).

Theorem 4. The optimal solution of the optimization system (13) is the unique solution of the problem (3).

Proof: The optimal solution of (13) is $(\tilde{u}, p) \in \tilde{V} \times Q$ such that $\text{div} \tilde{u} = 0$, then

$$\int (\text{div} \tilde{u}) q = 0 \text{ or } b(\tilde{u}, q) = 0, \quad \forall q \in Q$$

So, the optimal solution of (13) is the solution of (3).

In the Galerkin method, for solving (7) using finite element approximation requires a lot of computations to construct the space of basis functions (\tilde{V}_h, Q_h) . But, here we choose the space $\tilde{V}_n \subset (H_0^1(\Omega))^2$ of basis functions easily such that the boundary conditions are satisfied and $M_m \subset L_2(\Omega)$. The new method leads to the solution $p_m \in L_0^2(\Omega)$. We approximate the problem (13) by the discrete problem:

find $(\tilde{u}_n, p_m) \in \tilde{V}_n \times Q$ such that:

$$\begin{aligned} &\text{Minimize} \|\text{div} \tilde{u}_n\|_{L^2(\Omega)}^2 \\ &\text{subject to} \\ &a(\tilde{u}_n, \tilde{v}_n) + b(\tilde{v}_n, p_m) = (\tilde{f}, \tilde{v}_n), \quad \forall \tilde{v}_n \in \tilde{V}_n \\ &\int p_m dx = 0 \end{aligned} \quad (14)$$

Similarity, we can show that the optimal solution of the problem (14) is the solution of discrete form of the problem (9).

We choose v in the form

$$\tilde{V}_n = \text{span} \{B(x, y)\tilde{\phi}_i : i = 1, 2, 3, \dots, n\}$$

where $\tilde{\phi}_i$ are independent and $B(x, y)$ is a known function such that $B(x, y)\tilde{\phi}_i$ is equal to zero on the boundary. Thus we take the approximation solution \tilde{u}_n in the form

$$\tilde{u}_n = B(x, y) \sum_{i=1}^n c_i \tilde{\phi}_i$$

Also, we write the approximation solution p_m as a linear combination of independent functions ψ_j

$$p_m = \sum_{j=1}^m d_j \psi_j$$

By substituting \tilde{u}_n and p_m in (14), the optimization problem is transformed into the following quadratic programming:

$$\begin{aligned} &\text{Minimize} \frac{1}{2} C' H C \\ &\text{subject to} \\ &AC = b \end{aligned} \quad (15)$$

where $C = [c_1, c_2, \dots, c_{2n}, d_1, d_2, \dots, d_m]$, H is a $(2n+m) \times (2n+m)$ symmetric semi definite matrix, A is a $(2n+1) \times (2n+m)$ matrix.

5. Solving QP Problem

Consider the following QP problem:

$$\begin{aligned} & \text{Minimize } \frac{1}{2} x^T H x \\ & \text{subject to} \\ & Ax = b \end{aligned} \quad (16)$$

where H is an $m \times m$ symmetric positive semidefinite matrix, A is an $n \times m$ matrix and $\text{Rank}(A) = m$, $b \in R^n$, $x, a \in R^m$. The Karush-Kuhn-Tucker conditions of the problem (16) are:

$$\begin{aligned} Ax &= b, \\ A^T y - Hx &= 0 \end{aligned} \quad (17)$$

For solving the system (17), we use the following neural network model

$$\begin{aligned} \frac{dx}{dt} &= -H(x + k \frac{dx}{dt}) + A^T(y + k \frac{dy}{dt}) \\ \frac{dy}{dt} &= b - A(x + k \frac{dx}{dt}), \end{aligned} \quad (18)$$

The details are given in [14].

6. Numerical Results

Example: We consider the problem (1) with the unit square $\Omega = (0,1) \times (0,1)$ and with the following smooth exact solution

$$\begin{aligned} u_1 &= 10x^2y(1-x)^2(1-3y+2y^2) \\ u_2 &= -10y^2x(1-y)^2(1-3x+2x^2) \\ p &= x^2 + y^2 + x + y - \frac{20}{3}xy. \end{aligned}$$

We solve this problem by the method described in previous section and use $\psi_i \in P_2(\Omega)$ (polynomials of degree ≤ 2) and $\phi_i \in Q_2(\Omega)$ (polynomials of degree ≤ 2 in each of the variables). This means that $n = 9$ and $m = 5$. Also, we compare our results with least-square finite element ([15]) with $h = \frac{1}{64}$. The numerical results have been shown in **Table 1** for different viscosities.

The errors of the exact and approximation solutions for $\nu = 1$ are depicted in **Figures 1-3**.

Table 1. Numerical results.

7. Conclusions

In this paper we transformed the Stokes problem into a quadratic programming problem, and by solving it, we obtained the velocity and pressure as a linear combination of independent functions. The advantages of this method over the usual finite element method are the differentiability of the approximation solution, and computational work which is less than usual finite element. The performance of the scheme and the accuracy of the results are evaluated by compared with the reliable numerical in literature. The preliminary results presented in this paper show a promising future for the method. Yet more elaborations are required for identifying a systematic way of defining the solution function, which remains for future studies.
