Abstract
In this paper, multidimensional weakly singular integrals are solved by using rectangular quadrature rules which base on quadrature rules of one dimensional weakly singular and multidimensional regular integrals with their Euler-Maclaurin asymptotic expansions of the errors. The presented method is suit for solving multidimensional and singular integrals by comparing with Gauss quadrature rule. The error asymptotic expansions show that the convergence order of the initial quadrature rules is $O(h^{\alpha+i})$, where $-1 \leq \alpha_i \leq 0$.

The order of accuracy can reach to $O(h^0)$ by using extrapolation and splitting extrapolation, where $h$ is the maximum mesh width. Some numerical examples are constructed to show the efficiency of the method.

Keywords
Multidimensional Weakly Singular Integrals, Euler-Maclaurin Errors, Asymptotic Expansions, Splitting Extrapolation

1. Introduction
It is well known that multidimensional singular integrals are models arising in diverse engineering problems and mathematical applications. For example, in the boundary element fracture analysis problem, elasticity problem [1], bimaterial interfacial cracks [2] and wedge-sharped bimaterial interface [3], etc. Few of these integrals and equations can be solved explicitly, it is necessary to find a good numerical method. At present, there are many numerical techniques to calculate one-dimensional singular integrals or integral equations, such as collocation method [4], Gaussian quadrature method [5] [6], mechanical quadrature

*This work was supported by the National Natural Science Foundation of China (11371079).
method [7] [8]. The Gauss-quadrature rules are considered to be a good choice for solving high dimensional integrals because they were accurate for polynomial approximation and the cost is low. However, Gaussian formula is not suitable for dealing with more than five-dimensional problems. So, we give a new algorithm for solving the following integral

\[ I(F(x)) = \int_{a_1}^{b_1} \cdots \int_{a_s}^{b_s} F(x_1, \ldots, x_s) \, dx_1 \cdots dx_s, \]  

where \( F(x_1, \ldots, x_s) = \frac{f(x_1, \ldots, x_s)}{\prod_{i=1}^{s} |x_i - t_i|^\mu_i} \), \( t_i \in [a_i, b_i] \), \( 0 < \alpha_i < 1 \) for \( i = 1, \ldots, s \).

The structure of this paper is as follows: In Section 2, we give quadrature rules for weakly singular integral with multivariate errors asymptotic expansions. In Section 3, we construct the splitting extrapolation algorithm. In Section 4, some examples are given to illustrate the validity of the proposed method. Section 5 concludes the paper with a brief summary.

2. Multi-Parameters Asymptotic Expansions of the Errors for Weakly Singular Integrals

In this part, we mainly consider multidimensional weakly singular integrals. We give the corresponding results of multidimensional weakly singular integrals according to the quadrature formula and asymptotic expansions of the errors of one-dimensional integrals.

**Theorem 1.** If \( f(x_1, \ldots, x_s) \in C^2 \) on the interval \( [a_1, b_1] \times \cdots \times [a_s, b_s] \), and we assume that \( F(x_1, \ldots, x_s) = \frac{f(x_1, \ldots, x_s)}{\prod_{i=1}^{s} |x_i - t_i|^\mu_i} \), \( t_i \in [a_i, b_i] \), \( i = 1, \ldots, s \),

\[ F_1(x_1, \ldots, x_s) = \frac{f(x_1, \ldots, x_s)}{|x_1 - t_1|^\mu_1}, \quad F_2(x_1, \ldots, x_s) = \frac{f(x_1, \ldots, x_s)}{|x_2 - t_2|^\mu_2}, \]

\[ I(F(x)) = \int_{a_1}^{b_1} \cdots \int_{a_s}^{b_s} F(x_1, \ldots, x_s) \, dx_1 \cdots dx_s, \quad 0 < \alpha_i < 1. \]  

Then we have the following asymptotic expansions of the errors

\[ E(h) = I(F(x)) - Q(h) = \sum_{0 \leq \mu \leq s-1} \sum_{0 \leq \nu \leq s-1} A_{\mu\nu} h^{2\mu} + B_{\mu\nu} h^{2\mu+2\nu+1} + O\left(h_0^{2l}\right), \]  

where \( h = (h_1, \ldots, h_s) \), \( h_0 = \max_{1 \leq i \leq s} \{h_1, \ldots, h_s\} \), \( h_i = \frac{b_i - a_i}{N_i} \), \( i = 1, \ldots, s \), \( a = \{\sum_{i=1}^{s} k_i e_i \mid e_i = (0, \ldots, \alpha_i, \ldots, 0), k_i = 0 \text{ or } 1\} \).

**Proof:** We prove the theorem by the mathematic induction method. First, the conclusion is obvious right for \( k = 1 \). Now, we assume that the result also holds when \( k = s - 1 \). Next, we just need to prove the case of \( k = s \).
where $\mathbf{h} = (h_2, \cdots, h_n)$, $A_\mathbf{x}(x_i)$, $B_\mathbf{x}(x_i)$ are functions which are independent of $\mathbf{h}$. The integral can be written as

$$I(F(x)) = h_1 \sum_{i=1}^{N_1} \frac{1}{|x_2 - t_i|^p} \cdots h_n \sum_{i=1}^{N_n} \frac{1}{|x_n - t_i|^p} \int_{t_i}^{h} f(x_1, x_2, \cdots, x_n) \, dx_i$$

$$+ \sum_{\ell \in \mathcal{C}_1} \mathbf{h}^\ell \int_{t_i}^{h} A_\mathbf{x}(x_i) \, dx_i + \sum_{0 \in \mathcal{C}_1} \mathbf{h}^{2\mu + \alpha \gamma - 1} \int_{t_i}^{h} B_{\alpha \gamma}(x_i) \, dx_i$$

$$+ O(h_0^2) \int_{t_i}^{h} \frac{1}{|x_i - t_i|^p} \, dx_i = I_1 + I_2 + I_3 + I_4.$$  

we consider $I_1$

$$I_1 = h_1 \sum_{i=1}^{N_1} \frac{1}{|x_2 - t_i|^p} \cdots h_n \sum_{i=1}^{N_n} \frac{1}{|x_n - t_i|^p} \int_{t_i}^{h} f(x_1, x_2, \cdots, x_n) \, dx_i$$

$$= h_1 \sum_{i=1}^{N_1} \frac{1}{|x_2 - t_i|^p} \cdots h_n \sum_{i=1}^{N_n} \frac{1}{|x_n - t_i|^p} \left\{ h_1 \sum_{i=1}^{N_1} \frac{f(x_1, \cdots, x_n)}{|x_i - t_i|^p} ight\}$$

$$+ \sum_{\mu = 1}^{l-1} A h_2^\mu + \sum_{\mu = 1}^{l-1} B h_2^{2\mu + \alpha \gamma - 1} + O(h_0^2).$$

then $I_{11}$ can be represented as

$$I_{11} = h_1 \sum_{i=1}^{N_1} \frac{1}{|x_2 - t_i|^p} \cdots h_n \sum_{i=1}^{N_n} \frac{f(x_1, \cdots, x_n)}{|x_i - t_i|^p}.$$  

We need to consider the following formula

$$h_2 \sum_{i=1}^{N_1} \frac{1}{|x_2 - t_i|^p} \cdots h_n \sum_{i=1}^{N_n} \frac{1}{|x_n - t_i|^p}$$

$$= \int_{t_i}^{h} \cdots \int_{t_i}^{h} \frac{1}{\Pi_{i=2}^{N_n} |x_i - t_i|^p} \, dx_2 \cdots dx_n + \sum_{1 \in \mathcal{C}_1} A h_2^\mu + \sum_{0 \in \mathcal{C}_1} B h_2^{2\mu + \alpha \gamma - 1} + O(h_0^2).$$

we know the above equation is obviously right by induction. Next, we calculate $I_{12}$

$$I_{12} = h_2 \sum_{i=1}^{N_1} \frac{1}{|x_2 - t_i|^p} \cdots h_n \sum_{i=1}^{N_n} \frac{1}{|x_n - t_i|^p} \sum_{\mu = 1}^{l-1} A h_2^\mu$$

$$= \sum_{\mu = 1}^{l-1} A h_2^\mu \left\{ \int_{t_i}^{h} \cdots \int_{t_i}^{h} \frac{1}{\Pi_{i=2}^{N_n} |x_i - t_i|^p} \, dx_2 \cdots dx_n ight\}$$

$$+ \sum_{1 \in \mathcal{C}_1} A h_2^\mu + \sum_{0 \in \mathcal{C}_1} B h_2^{2\mu + \alpha \gamma - 1} + O(h_0^2).$$

The same as $I_{12}$ we can easy obtain

$$I_{13} = \sum_{\mu = 1}^{l-1} B h_2^{2\mu + \alpha \gamma - 1} + \sum_{1 \in \mathcal{C}_1} A h_2^\mu + \sum_{0 \in \mathcal{C}_1} B h_2^{2\mu + \alpha \gamma - 1} + O(h_0^2).$$
Now, we consider $I_2, I_3, I_4$

\begin{align}
I_2 &= \sum_{l=0}^{p-l-1} \mathcal{H}_{y}^{-p} \int_{h}^{h_{l+1}} \frac{A_p(x_l)}{|x_l-t_l|} dx_l = \sum_{l=0}^{p-l-1} A_p \mathcal{H}_{y}^{-p}, \\
I_3 &= \sum_{l=0}^{p-l-1} \mathcal{H}_{y}^{-p+1} \int_{h}^{h_{l+1}} \frac{B_{p}(x_l)}{|x_l-t_l|^{
u_{p}+1}} dx_l = \sum_{l=0}^{p-l-1} B_{p} \mathcal{H}_{y}^{-p+1}, \\
I_4 &= \int_{h}^{h_0} \frac{1}{|x_l-t_l|} dx_l O(h_0^2) = O(h_0^2).
\end{align}

Now, we obtain the following equation by taking the $I_1, I_2, I_3, I_4$ and $I_{11}, I_{12}, I_{13}, I_{14}$ into Equation (4)

\begin{align}
I(F(x)) - O(F((x))) &= \sum_{l=0}^{p-l-1} A h^2 + \sum_{l=0}^{p-l-1} B h^{2+\nu_{p}+1} + O(h_0^2),
\end{align}

where $A, B$ are constant which are independent of $h = (h_1, \ldots, h_s)$. The proof has been completed.

### 3. Splitting Extrapolation Algorithm

Now, we introduce the splitting extrapolation algorithm

\begin{align}
I(f) &= Q(h) + \sum_{l=0}^{p-l-1} A_l h^2 + \sum_{l=0}^{p-l-1} B_l h^{2+\nu_{l}+1} + \sum_{2c(p)+2m} A_m h^2
\end{align}

where $Q(h) = h \sum_{l=0}^{p-l-1} \sum_{i=0}^{p-l-1} f((i_l + \beta_l) h_{l+1}, \ldots, (i_k + \beta_k) h_k), \quad a' = \left\{ \sum_{l=0}^{p-l-1} k_l e_l | k_l = 0 \text{ or } 1, e_l = (0, \ldots, p, \ldots, 0), k = k_1 + \cdots + k_s \geq 2 \right\}.$

First, we have to eliminate the minimum term of the errors expansions. According to (2), we can easily find that $h_0^2$, $i = 1, \ldots, s$ are low order terms when $|\nu| = 0$. Assuming that $\alpha_j + 1 = \min_{i \in [0, s]} \{ \alpha_j + 1 \}$, and we use splitting extrapolation in the direction of $x_i$

\begin{align}
I_{13}^{(0)}(f) &= Q(h_i, \ldots, \frac{h_i}{2}, \ldots, h_i) + \sum_{l=0}^{p-l-1} A_l h^2 + \sum_{l=0}^{p-l-1} B_l h^{2+\nu_{l}+1}
\end{align}

Then, we use $\left( 2^{\nu_{l}+1} I_{13}^{(0)}(f) - I(f) \right) / (2^{\nu_{l}+1} - 1)$ and obtain the following equation

\begin{align}
I_{13}^{(1)}(f) &= Q_{13}^{(1)}(h_i, \ldots, h_i) + \sum_{l=0}^{p-l-1} A_l h^2 + \sum_{l=0}^{p-l-1} B_l h^{2+\nu_{l}+1}
\end{align}
where \( Q_{1,1}^{(1)} = \frac{2^{\alpha_i+1} Q(h_i, \cdots, h_i) - Q(h_i, \cdots, h_i)}{2^{\alpha_i+1} - 1} \), and \( A_{ij}, B_{ij}, i = 1, \cdots, s \) are constants which are unrelated to \( h \). We can obtain higher accuracy and convergence order by repeating the above process.

4. Examples

In this section, we give some examples to illustrate the efficiency of the proposed method.

**Example 1.** We consider the following \( s \)-dimensional integral \([9]\)

\[
\int_0^1 \cdots \int_0^1 \exp(x_1 + \cdots + x_s) dx_1 \cdots dx_s = (e-1)^s. \tag{18}
\]

We give the numerical results of the splitting extrapolation of types 1 and 2 and Gauss quadrature methods. **Table 1** gives the relative error (RE) and CPU time for different dimension \( (s) \) and splitting times \( (m) \). From the **Table 1**, we can find that the splitting extrapolation method is suit for solving high dimensional integrals, and Gauss quadrature rule is difficult for solving more than five dimensional problems.

**Example 2.** we consider the following integral

\[
\int_{0}^{1} \int_{0}^{1} \int_{0}^{1} \int_{0}^{1} \frac{x_1^{1/3} x_2^{1/3} x_3^{1/3} \left(x_4 - \frac{3}{2}\right)^{1/3}}{(x_5 - 1)^{1/4} (x_6 - 1)^{1/4} (x_7 - 1)^{1/3}} dx_1 \cdots dx_7 = -6 \left(2^{5/15} \left((-1)^{2/3} - 1\right)\right). \tag{19}
\]

This is a high dimensional weakly singular integral which can be solved by splitting extrapolation algorithm. In **Table 2**, we give the absolute errors and convergence orders for splitting extrapolation of each step. From the table, we can find that the convergence order can reach to \( O(h_i^4) \) by using splitting extrapolation twice, and the orders are coincide with the theoretical analysis. In **Figure 1**, we give the curves of absolute errors for each splitting extrapolation. From the Vertical direction, the images sink and the slopes of the curves increase with the increasing of the splitting times, which indicates that the errors decrease and the convergence orders increase. From the horizontal coordinate, the errors are reduced with the increasing of the node numbers. This shows that the splitting extrapolation not only enhance the numerical precision but also the order of accuracy.

**Table 1.** Numerical results with errors and orders of accuracy for Example 2.

5. Conclusion

In this paper, we give the quadrature formula with the asymptotic expansions of errors for solving multidimensional integrals with arbitrary points weakly singular. According to the asymptotic expansions of errors, we construct splitting extrapolation algorithm to improve the accuracy and the convergence order of the numerical results. By comparing the numerical results of our method with Gauss quadrature method, we can conclude that the splitting extrapolation method is efficient for solving high dimensional integral and weakly singular integrals. Next, we consider how to use the method to deal with boundary integral and differential equations.
