ABSTRACT

One of the very important functions of three-phase inverter is to maintain the symmetric three-phase output voltage when the three-phase loads are unbalanced. Although the traditional symmetrical component decomposing and superimpose theory can keep the voltage balance through compensating the positive-, negative- and zero-sequence components of the output voltage of inverter, however, this method is time-consuming and not suitable for control. Aiming at high power medium frequency inverter source, a \textit{P}+\textit{Resonant} (Proportion and Resonant) controller which ensured a balanced three phase output voltage under unbalanced load is proposed in this paper. The regulator was proved to be applicable to both three-phase three-wire system and three-phase four-wire system and developed two methods of realization. The simulation results verified that this method can suppressed effectively the output voltage distorted caused by the unbalanced load and attained a high quality voltage waveforms.

1. Introduction

In recent decades, with the rapid development of power electronics technology and the improving requirements of electric device performance in trades and industries, the inverter technology are increasing widespread used in multi-domain. Accordingly, there have more and more requirements for inverter power. Many electric devices of industries are not use directly grid but inverters as their power source. Some important power-consuming departments and electric devices, especially in high power medium frequency system, such as vessel and aircraft, require more high quality of the source, demand the voltage, frequency and waveform accurate, have a good dynamic state performance and no any disturbance from the source.

In three-phase system, however, unbalanced instances can occur in power systems for a variety of cases, such as, three imbalanced load, unsymmetrical parameters of three-phase filter, single-phase load, and so on. Unbalanced loading causes negative- and zero-sequence currents (in four-wire systems) to flow in the power system. For ideal sources this would not be a problem. However, inverter source systems, especially high power 400Hz inverter source systems, with finite output impedances, will experience voltage distortion in the form of phase voltage imbalance and phase shift due to unbalanced loading. At worst, unbalanced voltages can cause malfunction and even failure of power-consuming equipment. Thus, in inverter-fed power systems, it is the responsibility of the inverter to ensure that certain tolerances on phase voltage imbalance at the load terminals are met under specified loading conditions. Reference [1] proposed a method of extending controller bandwidth. By transforming \textit{abc} to \textit{dqo}, the negative- and zero-sequence components can be view as a disturbance of 2\textit{w} and \textit{w} respectively. By utilizing controllers with bandwidths greater than the frequency of the disturbances, some attenuation will be achieved and the output voltage balance may be ensured. While this may be possible in low power 50/60Hz inverters, it would be very difficult, and likely impossible, to accomplish in high power inverters due to the difficulties of improving the switching frequency. The impossibility of this option is amplified for inverters with high output fundamental frequencies, such as the inverter under study. Reference [2] put forward a method of load current feedforward control. By using load current feedforward control, the output voltage balance can be
promised. In general, true feedforward assumes that the variables that are fed forward are known and independent of the controlled system. However, in the case of the load currents feedforward, the assumptions are false, because the load currents are closely coupled to the plant state variables. Thus, this feedforward control in fact forms a feedback loop. As a result, the system stability is affected and must be examined. Reference [3] proposed a double dq transform control method. Although this method can eliminate the negative-sequence component, it can do nothing for zero-sequence component. Moreover, this control strategy is time-consuming and not suitable for control.

Firstly, this paper analyzed the mathematical model of the three-phase inverter and the application of the symmetrical component decomposing in engineering. As for three-phase two H-bridge units cascaded topology, a resonant controller is proposed and simulations on a three-phase 30kVA medium frequency inverter under unbalanced load are carried out. The results verified that the resonant controller can be used to satisfy completely output voltage balance under any unbalanced loads.

2. Model of Three-Phase Inverter Source and Unbalance Analysis

The topology of three-phase inverter under study is shown in Figure 1. Only phase A is presented detailedly here for the sake of space limitation. Each phase consist of DC bus voltage U_d, two H-bridge inverter, two transformer T, filter inductor L, filter capacitor C and load R which can be balanced load, unbalanced load, single-phase load, and so on. r represent the integrative effect of ESR of filter inductor, dead time of the inverter, and so on. Unipolar modulation is adopted in the single H-Bridges whose outputs are in series at secondary of H-bridge and interleaving control is done between two transformers. There are 90 phase degree difference between corresponding carrier waves of two H-Bridges and the modulating waves are the same, so the equivalent switching frequency of inverter is four times of the device switching frequency and the output voltage has five-level waveforms that means harmonics content in output voltage resulting from the switching is reduced.

In Figure 1, u_{Ta}, u_{Tb}, u_{Tc} represent the output phase voltage of transformer. u_{0a}, u_{0b}, u_{0c} represent the three voltage of filter capacitor, i_{1a}, i_{1b}, i_{1c} represent the three current of filter inductor and i_{0a}, i_{0b}, i_{0c} represent the three line current. According to KCL and KVL, Formula (1) can be written out:

\[
p\begin{bmatrix} u_0 \\ i_1 \\ u_c \end{bmatrix} = \begin{bmatrix} 0 & \frac{1}{C}I_3 \\ -\frac{1}{L}I_1 & -\frac{r}{L}I_1 & \frac{1}{L}I_1 \\ \end{bmatrix} \begin{bmatrix} u_0 \\ i_1 \\ u_c \end{bmatrix} + \begin{bmatrix} 0 \\ -\frac{1}{C}I_3 \\ 0 \end{bmatrix} \begin{bmatrix} u_o \\ i_o \end{bmatrix}
\]

(1)

where \( p \) denotes differential operator. \( u_0 = [u_{0a} \ u_{0b} \ u_{0c}]^T \) denotes the output voltage vector of inverter, \( i_1 = [i_{1a} \ i_{1b} \ i_{1c}]^T \) denotes current vector of filter inductor, \( u_c = [u_{c0} \ u_{c1} \ u_{c2}]^T \) denotes the output voltage vector of transformer, \( i_0 = [i_{0a} \ i_{0b} \ i_{0c}]^T \) denotes the current vector of load and I_3 denotes a unit matrix of three by three.

If u_{0a}, u_{0b}, u_{0c} and i_{1a}, i_{1b}, i_{1c} were taken as state variables, then Formula (1) and (2) make up of the plant state equation of Figure 1.

\[
y = [u_{0a} \ u_{0b} \ u_{0c}]^T
\]

(2)

Unbalanced output phase voltages or currents phasor can be symmetrically decomposed into their positive-, negative- and zero-sequence components. Assume V_a, V_b and V_c represent three phase voltage phasor, then:

\[
\begin{bmatrix} V_a \\ V_b \\ V_c \end{bmatrix} = \begin{bmatrix} V_{a+} \\ V_{b+} \\ V_{c+} \end{bmatrix} + \begin{bmatrix} V_{a-} \\ V_{b-} \\ V_{c-} \end{bmatrix} + \begin{bmatrix} V_{a0} \\ V_{b0} \\ V_{c0} \end{bmatrix}
\]

(3)

\[
\begin{bmatrix} V_{a+} \\ V_{b+} \\ V_{c+} \end{bmatrix} = V_d \begin{bmatrix} 1 & \alpha & \alpha^2 \end{bmatrix}^T
\]

\[
\begin{bmatrix} V_{a-} \\ V_{b-} \\ V_{c-} \end{bmatrix} = V_d \begin{bmatrix} 1 & \alpha^2 & \alpha \end{bmatrix}^T
\]

(4)

\[
\begin{bmatrix} V_{a0} \\ V_{b0} \\ V_{c0} \end{bmatrix} = V_0 \begin{bmatrix} 1 & 1 & 1 \end{bmatrix}^T
\]

(5)

where \( \alpha = e^{-j\frac{2\pi}{3}} \), subscript a, b, c represent three
phase electricity respectively, subscript +, -, 0 represent positive-, negative- and zero-sequence components respectively.

3. Resonant Regulator

It is known from analysis aforementioned that due to near zero impedance which ideal sources possess, the voltage dropping of impedance caused by negative- and zero-sequence current components due to unbalanced load is almost zero and unbalanced load has little influence on ideal sources. So if the output voltage of inverter is not suffer from the unbalanced load is expected, the output impedance of inverter source must be near zero too. It is known from control theory that if a near zero impedance of a system is expected, the open loop gain of the control system must be attain infinite at certain signal frequency.

3.1 Resonant Controller with $\alpha\beta\gamma$ as Input and Output Variable

Figure 2 is the resonant controller of three-phase system. By transforming abc to $\alpha\beta$, the output voltage errors of abc coordinate can be transfer to $\alpha\beta$ coordinates variable $e_{\alpha\beta}$ ($e_{\alpha\beta} = e_{\alpha} + je_{\beta}$). Following the scheme of Figure 2(a), the output voltage errors $e_{\alpha\beta}$ ($e_{\alpha\beta} = e_{\alpha} + je_{\beta}$) in $\alpha\beta$ coordinates are first converted into synchronous reference frame quantities $e_{+} (e_{+} = e_{\alpha} + je_{\phi})$, $e_{-} (e_{-} = e_{\alpha} - je_{\phi})$ using both positive- ($dqk+$) and negative- ($dqk-$) sequence transformations rotating at angular frequency $\omega = k\omega$ (i.e., $e_{+} = e^{j\omega t} e_{\alpha}^0$, $e_{-} = e^{-j\omega t} e_{\alpha}^0$) where $k$ is the order of the generic harmonic to be compensated and $\omega$ is the fundamental angular frequency. All synchronous reference frame errors ($e_{\alpha+}, e_{\alpha-}, e_{\phi+}, e_{\phi-}$) are then compensated by regulators $H_{\text{DC}}(S)$, which ensure zero steady-state errors for each positive- and negative-sequence harmonic component. Then, the output of each regulator ($y_{\alpha+}, y_{\alpha-}, y_{\phi+}, y_{\phi-}$) is converted back to the stationary reference frames and possibly adding a leading angle $\phi_k$ which compensates for the delay of the remaining process. The structure is complicated which need compensate for each order harmonics including positive- and negative- sequence components. Moreover, coupling may be exist between the d and q axis variables.

There will exist zero-sequence component if the three-phase system is imbalanced. Of course, any possible zero-sequence component cannot be compensated in Figure 2. However, zero sequence component can be control by the resonant controller also. This will be discussed later.

Some simplifications of the theoretical scheme of Figure 2(a) are possible [4,5]. First, it is easy to verify that the compensation of both positive- and negative-sequence harmonic components for a generic harmonic $k$ is equivalent to the synchronous demodulation of the $\alpha\beta$ components, shown in Figure 2(b), as long as all regulators $H_{\text{DC}}(S)$ in Figure 2(a) and (b) have the same transfer function. Secondly, even the scheme of Figure 2(b) can be further simplified since it is equivalent to the scheme of Figure 2(c) with stationary-frame regulators $H_{\text{ACK}}(S)$. The proportion term can be put outside the transform due to the proportion is same in stationary reference frame and synchronous reference frame.

By deducing, the transform formula $H_{\text{ACK}}(S)$ is [4]:

$$H_{\text{ACK}}(S) = \cos\varphi_k \left[H_{\text{DC}}(S - jk\omega) + H_{\text{DC}}(S + jk\omega)\right] + j\sin\varphi_k \left[H_{\text{DC}}(S - jk\omega) - H_{\text{DC}}(S + jk\omega)\right]$$

(6)

If

$$H_{\text{DC}}(S) = \frac{K_n}{S}$$

(7)

Then

$$H_{\text{ACK}}(S) = 2K_n \left(\frac{S \cos\varphi_k - k\omega \sin\varphi_k}{S^2 + (k\omega)^2}\right)$$

(8)

If the delay compensating is not take into account in Formula (8), then

![Bode plot of resonant regulator](image)

The resonant controller can be used to deal with all \( \alpha \beta \gamma \) axis variable. The control block is shown in Figure 3.

The matrix form is shown in Formula (10)

\[
\begin{bmatrix}
Y_{\alpha}(S) \\
Y_{\beta}(S) \\
Y_{\gamma}(S)
\end{bmatrix} =
\begin{bmatrix}
\frac{2K_{S}}{S^{2} + \omega^{2}} & 0 & 0 \\
0 & \frac{2K_{S}}{S^{2} + \omega^{2}} & 0 \\
0 & 0 & \frac{2K_{S}}{S^{2} + \omega^{2}}
\end{bmatrix}
\begin{bmatrix}
E_{\alpha}(S) \\
E_{\beta}(S) \\
E_{\gamma}(S)
\end{bmatrix}
\tag{10}
\]

It is can be seen from (10) that the term of non-diagonal is zero which means there are no coupling among \( \alpha \beta \gamma \) variable and can be decoupled as single-phase.

The bode diagram of Formula (9) where k is equal to one is shown in Figure 4(a). It can be seen from Figure 4(a) that the regulator has an infinite gain (it is a finite value in the bode diagram due to simulation step and truncation error) at certain frequency. Then the gain of open loop which including the resonant controller will achieve infinite (as for unit negative feedback system, the gain of open loop is equal to transfer function of controller multiply transfer function of object) and zero steady state error between output voltage and reference voltage can be promised.

It is also noted that the controller presented in (9) has a transfer function similar to that presented by Sato et al. [7] which has a resonant transfer function given by

\[
H_{AC}(S) = \frac{2K_{II}\omega}{S^{2} + (\omega)^{2}}
\tag{11}
\]

Sato’s transfer function also has infinite gain at the resonant frequency and hence can be used to suppress the output voltage distorted caused by the unbalanced loads. However, it in particular introduces a phase shift of 180\(^\circ\) into the system, compared to the 90\(^\circ\) shift of the \( P+\)Resonant system, as illustrated in Figure 4(b). In closed loop operation this 180\(^\circ\) phase shift results in a poorer phase margin and a poor transient performance for this regulator compared to the approach presented here.

The resonant controllers which induced before are with

\(\alpha\beta\gamma\) as input and output variable. However, practical three-phase systems are with abc as input and output variable. The deduction of the relations of controller with abc as input and output variable and controller with \(\alpha\beta\gamma\) as input and output variable is shown as follows:

It can be known from stationary coordinate transformation theoretics,

\[
T_{\text{abc}}^{\alpha\beta\gamma} = \frac{2}{\sqrt{3}} \begin{bmatrix}
1 & -\frac{1}{2} & -\frac{1}{2} \\
0 & \sqrt{3} & -\frac{\sqrt{3}}{2} \\
\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}}
\end{bmatrix}
\]  

(12)

and

\[
T_{\text{abd}}^{\alpha\beta\gamma} = \frac{2}{\sqrt{3}} \begin{bmatrix}
1 & 0 & \frac{1}{\sqrt{2}} \\
-\frac{1}{2} & \frac{\sqrt{3}}{2} & \frac{1}{\sqrt{2}} \\
-\frac{1}{2} & \frac{\sqrt{3}}{2} & \frac{1}{\sqrt{2}}
\end{bmatrix}
\]  

(13)

So the relation of variable in abc coordinate and variable in \(\alpha\beta\gamma\) coordinate is:

\[
x_{\alpha\beta\gamma} = T_{\text{abc}}^{\alpha\beta\gamma} g x_{\text{abc}} \quad \text{and} \quad x_{\text{abc}} = T_{\text{abc}}^{\alpha\beta\gamma} g x_{\alpha\beta\gamma}
\]

Then

\[
Y_{\text{abc}} (S) = T_{\text{abc}}^{\alpha\beta\gamma} g Y_{\alpha\beta\gamma} (S) = T_{\text{abc}}^{\alpha\beta\gamma} g G_{\alpha\beta\gamma} (S) E_{\alpha\beta\gamma} (S)
\]

\[
= T_{\text{abc}}^{\alpha\beta\gamma} g G_{\alpha\beta\gamma} (S) T_{\text{abc}}^{\alpha\beta\gamma} g E_{\text{abc}} (S)
\]

\[
= G_{\text{abc}} (S) g E_{\text{abc}} (S)
\]

where

\[
G_{\text{abc}} (S) = T_{\text{abc}}^{\alpha\beta\gamma} g G_{\alpha\beta\gamma} (S) g T_{\text{abc}}^{\alpha\beta\gamma}
\]

If \(G_{\alpha\beta\gamma} (S)\) equal to Formula (10), Then

\[
G_{\text{abc}} (S) = \begin{bmatrix}
\frac{2K_S}{S^2 + \omega^2} & 0 & 0 \\
0 & \frac{2K_S}{S^2 + \omega^2} & 0 \\
0 & 0 & \frac{2K_S}{S^2 + \omega^2}
\end{bmatrix}
\]  

(15)

It can be seen from (15) that the element of non-diagonal is zero, which means there are no coupling among abc variable and can be decoupled as single-phase.

It must be emphasis on that the system must be three-phase four-wire system when apply Formula (10) or (15). This is because zero-sequence component can only be compensated in three-phase four-wire system. As for three-phase three-wire system, Formula (10) or (15) can not be used directly. However, by weeding the zero-sequence component of feedback variable and ensuring the input variable of \(\gamma\) axis equal to zero, Formula (10) or (15) can be used in three-phase three-wire system. Moreover, in general, line to line voltage can only be gotten in three-wire system and phase voltage which educed from line to line voltage satisfy automatically the condition that input variable of \(\gamma\) axis equal to zero.

4. Simulation Investigations

In order to illustrate the resonant controller is effective on unbalanced load, the proposed control strategy has been investigated using MATLAB/Simulink simulations on both three-phase three-wire system and three-phase four-wire system. The load is Y or Yn connected and loads of phase A, B and C are 1.5Ω, 1.5Ω and 15Ω respectively. Table 1 defines the parameters used in simulations.

The output voltage waveforms of three-phase four-
The error voltage and output voltage $V_o$, the reference voltage $V_{ref}$ waveforms of three-phase four-wire system under resonant controller are shown in Figure 6(a). It can be seen from (a) that the error is almost zero and the output voltage is superposition with reference voltage which proved the correct of analysis aforementioned. In order to compare, Figure 6(b) gave the waveforms under proportion regulator. It can be seen from (b) that there are obvious steady state amplitude and phase error between the reference voltage and the output voltage.

5. Conclusions

This paper analyzed the output voltages distortion mechanism under unbalanced load, a three-phase two H-bridge units cascaded topology is presented and the equivalent switching frequency of inverter is improved effectively. A P+Resonant controller which ensured a balanced three phase output voltage under unbalanced load is proposed for high power medium frequency inverter sources. The regulators proved to be applicable to both three-phase three-wire system and three-phase four-wire system and two methods of realization were developed. The simulation results verified that this method can suppressed effectively the output voltage distorted caused by the unbalanced load and attained a high quality voltage waveforms.
