Abstract

The study of own fields and charged particles motion and also charged fission splinters of a heavy nucleuses into nonrelativistic approximation is the subject of this article research. The main efforts are concentrated in quest of charged share components by the radioactive $\beta^-$-disintegration. The corresponding field equations and equations of motion in the nuclear electrodynamics processes are obtained and their solutions are found. Analysis of the microscopic equations is generalized to the level of the macroscopic description of continuous medium electrodynamics and is accompanied by quantum mechanical additions. The obtained theoretical results can be a basis for the further mathematical modelling of generation phenomenon of powerful directional electromagnetic fields on the toroid with external winding in the process of chain reaction fission and for the further creation of the nuclear electrogenerator (nuclegen) as a peculiar analogy to the quantum generator.

Subject Areas

Theoretical Physics, Modern Physics, Nuclear Physics

Keywords

Equations of Nuclear Electrodynamics, Charged Particles, Charged Fission Splinters

1. Introduction

At the beginning we should stop briefly on the structural description and the content of article sections. Sections 2 - 5 are devoted to the coverage of a behaviour for dotted charged particles and fission splinters within the classical nonrelativistic nuclear electrodynamics.

In Sections 2 and 3 the consecutive microscopic description on the level of
Maxwell-Lorenz fields equations and Newton-Lorenz equations of motion are carried out. Obtained in Section 2 results serve a foundation to the conclusion of laws for nonrelativistic nuclear electrodynamics of the charged fission splinters (Sections 3 and 4) and laws for continuous medium electrodynamics with the aid of macroscopic approach in consideration of statistical description (Section 5).

In Section 6 the nonrelativistic electrodynamic model is supplemented by consideration more realistic scheme connected with quantumomechanical conclusion of the microscopic equations for fields and motions of charged particles and charged fission splinters.

The important peculiarity of presented work is a definition and solution of fields equations and motion equations for fission splinters in consideration of charged share of radioactive inside nuclon $\beta^-$-disintegration effect [1], i.e. in consideration of emitted cascaded electrons but without consideration of $\gamma$-radiation [2] [3] [4]. We propose the toroid is the solenoid with the external winding. Moreover inside of this toroid all fragments of the nuclear disintegration remain in force. That is why light charges don’t may escape the system and therefore enter the formalism. Theoretical results of Sections 2 - 6 can be also the basis for the elaboration of possible mechanism of hypermotion realization [5]-[12].

Similar to quantum generation phenomenon and some other physical effects going on intensive avalanche-like scheme there are analogous processes occur by the chain fission of a heavy nucleuses [5] [9] [13] [14]: the vigorous growth of total number of neutrons, charged particles and charged fission splinters having enormous kinetic energy of motion is observed. This known phenomenon (charges motion in vacuum with great speed) is put into basis of nuclear electrodynamic effect.

On this theory principles may be constructed superpowerful energetical devices operating no on thermal interaction of various substances but exclusively on a basis of physical electronuclear conversions. Actually, it is matter of on principle new stage into energy development which at this point is named the nuclear electrodynamics.

As at laser technology the nuclear electrodynamic model for own functional beginning demands the preliminary ”power reprimand” in a state of external directional electromagnetic field for making of anisotropic backcloth with the passing of chain nuclear fission reaction in vacuum.

We suppose that the nuclear electrogenerator of direct action can be highly effective and reliable alternative to contemporary thermal nuclear reactor in the future. What is more, its role and meaning in subsequent wide and speedy pioneering of outer space, to all appearance, will be predominating as a basis component of arised compact hyperreactive accelerators [5] [9].

### 2. Fields and Motion of Charged Fission Particles

We are interested the calculation recipe of electric $E_i(R,t) \in \mathbb{R}^3$ and magnetic $B_i(R,t) \in \mathbb{R}^3$ fields in the point with coordinate $R \in \mathbb{R}^3$ at the time moment $t$. 
which are produced by the point-particles with charges \( Z_i \), three-dimensional coordinates \( R_i(t) \) and velocities \( \dot{R}_i(t) = v_i(t), i = 1, 2, \ldots \). It is known that given vector fields into Gaussian units system (taking into account of values in order \( 1/c \), where \( c \) is velocity of light, and of multiplicator \( 4\pi \) in the expression for potentials) can be written with the aid of microscopic Maxwell-Lorenz equations system in the following form

\[
\nabla E_i = \sum_i Z_i \delta (R_i - R),
\]

\[
-E'_i + \nabla \times B_i = \frac{1}{c} \sum_i Z_i \dot{R}_i \delta (R_i - R),
\]

\[
\nabla B_i = 0, \quad B'_i + \nabla \times E_i = 0.
\]

(1)

Here we denote: for the vector \( \nabla \) (the differential Hamiltonian operator) is the differentiation on three-dimensional spatial coordinate \( R \); the feature on top is the differentiation on \( ct \); notes \( xy \) and \( x \times y \) correspondingly mean scalar and vector products; \( \delta (R_i - R) \) is the delta-function from \( R_i - R \) including in the field sources.

To find solutions of Equation (1) introduce into consideration potentials. From the third Equation (1) we have for the vector potential \( a(R,t) \):

\[
B_i = \nabla \times a.
\]

(2)

Taking into account the fourth Equation (1) we obtain for the scalar potential \( \varphi (R,t) \):

\[
E_i = -\nabla \varphi - a'.
\]

(3)

After substitution of relations (2) and (3) into the first two Equation (1) ignoring of values in order \( 1/c^2 \) we derive

\[
\nabla \varphi + \nabla' a = -\sum_i Z_i \delta (R_i - R),
\]

\[
\nabla a - \nabla (\nabla a + a') = -\frac{1}{c} \sum_i Z_i \dot{R}_i \delta (R_i - R),
\]

(4)

where \( \Delta = \nabla \nabla = \nabla^2 \) is the Laplace operator.

Relations (2), (3) determine potentials \( a \) and \( \varphi \) ambiguously to an approximation of the calibrated equalities

\[
a_i = a + \nabla \psi, \quad \varphi_i = \varphi - \psi',
\]

where \( \psi \) is the some arbitrary function. Take advantage of given fact so that potential \( a \) and \( \varphi \) satisfied the Lorenz calibrated condition

\[
\nabla a + \varphi' = 0
\]

which permits Equations (4) to write in form of two independent Poisson equations on \( \varphi \) and \( a \). Ignoring of values in order \( 1/c^2 \) then we obtain

\[
\Delta \varphi = -\sum_i Z_i \delta (R_i - R), \quad \Delta a = -\frac{1}{c} \sum_i Z_i \dot{R}_i \delta (R_i - R).
\]

If for solution of this equations according to the work [2] to make use of relation...
\[ \Delta \frac{1}{|r|} = -4\pi \delta(r), \]

where \( r = r(x, y, z) \) is vector-radius of the point with coordinates \( x, y, z \) and \(|r| = \left( x^2 + y^2 + z^2 \right)^{1/2} \) is its the Euclidean length, then we may write potentials

\[
\varphi = \sum_i \frac{Z_i}{4\pi \sigma_i}, \quad a = \frac{1}{c} \sum_i \frac{Z_i R_i}{4\pi \sigma_i}.
\]

Further, we shall use relations (2) and (3). Then the nonrelativistic electromagnetic fields can be found as

\[
E_\ast = \sum_i E_i, \quad E_i = -\nabla Z_i,
\]

\[
B_\ast = \sum_i B_i, \quad B_i = \frac{1}{c} \nabla \times \frac{Z_i R_i}{4\pi \sigma_i},
\]

where through \( \sigma_i = |R_i - R| \) is denoted the distance between points with vector coordinates \( R_i \) and \( R \) in space \( \mathbb{R}^3 \).

Pay attention to that from relations (5) it follows that the field \( E_\ast \) is noncirculatory. Then in fourth equation of system (1) the value \( B' \) has a order \( \sqrt{c^2} \) and by it may ignore in considered nonrelativistic variant. Therefore in system (1) last equation may write as \( \nabla \times E_\ast = 0 \).

Denote \( (E(R_i,t), B(R_i,t)) \) the full electromagnetic field in the point \( R_i \) at time moment \( t \). This field is the sum of external field \( (E_0(R_i,t), B_0(R_i,t)) \) and internal fields of the charged particles \( (E_i(R_i,t), B_i(R_i,t)) \) in the given point.

The equation of \( i \)-th particle motion with mass \( m_i \) under the Lorenz force influence has a form

\[
m_i \ddot{R}_i = Z_i \left[ E(R_i,t) + \frac{1}{c} \dot{R}_i \times B(R_i,t) \right],
\]

where the notation

\[
E(R_i,t) = \sum_j E_j(R_i,t) + E_0(R_i,t),
\]

\[
B(R_i,t) = \sum_j B_j(R_i,t) + B_0(R_i,t)
\]

is used, moreover \( i \neq j, \sum_j E_j = E_\ast, \sum_j B_j = B_\ast \). The equation of motion (6) for nonrelativistic case taking into account the second line of the system (5) can be made more precise, namely

\[
m_i \ddot{R}_i = Z_i \left[ E(R_i,t) + \frac{1}{c} \dot{R}_i \times B_0(R_i,t) \right],
\]

where

\[
E(R_i,t) = -\sum_j \nabla_j \frac{Z_j}{4\pi \sigma_{ij}} + E_0(R_i,t), \quad B(R_i,t) = B_0(R_i,t),
\]

\( \sigma_{ij} = |R_i - R_j|, i \neq j \), \( \nabla_j \) is partial derivation on elements of the vector \( R_j \).

Thus, Equation (7) describes nonrelativistic motion of \( i \)-th charged particle,
in electromagnetic field of external sources and from the direction of other \( j \)-th particles, \( j = 1, 2, \cdots, j \neq i \), in the given point \( R_i \). Equation (7) can be attached to the canonical form

\[
\frac{\partial H}{\partial P_i} = \dot{R}_i, \quad \frac{\partial H}{\partial R_i} = -\dot{P}_i
\]

with aid of the Hamiltonian

\[
H = \sum_i \frac{p_i^2}{2m_i} + \sum_j \frac{Z_j Z_i}{8\pi\varepsilon_0} + \sum_j Z_i \left[ \varphi_0 (R_i, t) - \frac{P_i}{cm_i} \cdot A_0 (R_i, t) \right], \quad i \neq j,
\]

into the canonical terms of impulse variables \( P_i \), coordinate variables \( R_i \) and potentials (scalar \( \varphi_0 \) and vector \( A_0 \)) of external field.

### 3. Fields and Motion of the Charged Fission Splinters

Let us set the problem about conclusion of field equations and motion equations of the charged splinters (the united particles with internal nuclear structure) which are generated in consequence of the chain fission reaction. These compound united particles can be considered as many time ionizated positive ions for the reason electrons upsetting of the atom outer skin of divided substance.

For definition of the electromagnetic field of the charged fission splinters we shall be proceeding in own analysis from the field microscopic equations of isolated particles (1). Add to the index \( i \) the index \( k \). Then instead of the vector \( R_i \) we take the vector \( R_{ki} \) and expand it into the sum of two vectors:

\[
R_{ki} = R_k + r_{ki}, \quad \text{where} \quad k \text{ is the splinter index,} \quad i \text{ is the index of the particle of given splinter,} \quad R_k \text{ is the coordinate of the some fixed point (nucleus) of} \ k\text{-th splinter,} \quad r_{ki} \text{ is the internal coordinate of} \ ki\text{-th particle (its position) concerning the fixed point of} \ k\text{-th splinter.}
\]

But as distinct from the works [2] [3] [4] and the others here it is necessary to mean that considered charged compound fission splinters aren’t “the stable complexes” but are the powerfully nonsteady particles groups are exposed the pronounced instantaneous radioactive fission (the \( \beta \)-fission accompanied by the \( \gamma \)-radiation). Radioactive instability of the fission splinters in one’s turn leads to peculiar and simultaneously enough intricate deformation of the fields electromagnetic equations and the motion of these assembly particles. Thus, our problem is concluded in so that “to catch” the distinctive peculiarity of radioactive disintegration of the given instable particles and to obtain correct from mathematical and physical points of view the note of these equations.

Before to begin the equations synthesis we discuss just one more important moment of the theory. The problem of classical nonrelativistic electrodynamics is the registration of radioactive instability of the charged particles. It is well known that in the given case, \( i.e. \) when only parts up to the first order on \( \frac{1}{c} \) inclusive are taken into consideration, to count up the effect of radiation \( \gamma \)-radiation (the fading) turn out badly. This effect caused by “minus-field” (the retarding field) of the particle in nonrelativistic case is vanishingly small. In
connection with given exposition we try by the conclusion of equations to take into account the effect of charged radioactive disintegration but not of radio-active $\gamma$-eradiation accounting.

Subsequently it is important to distinguish between the individual charged particles in the $k$-th fission splinter in the point $R_k$ with the charges $Z_k$ and the charged nucleus in the point $R_k$ is exposed $\beta$-radioactive fission. We remind that the fission splinters are intensive $\beta$-eradiators, moreover the beta-fission is the subnucleonic process stipulated by poor interactions and proceeding for surplus neutrons of a splinter according to scheme: $n \rightarrow p + e^- + \bar{\nu}$, i.e. in free state on average life time in order of 17 minutes neutron decays into proton, electron and antineutrino. We note also that inside of nucleus the formation of neutron it is possible owing to additional energy is imparted to proton by other nucleons of nucleus: $p \rightarrow n + e^+ + \nu$, i.e. during $\beta^-$-fission when the process of proton fission inside of nucleus is occurs at expanse of nucleus energy into neutron, positron and neutrino.

Therefore, we indicate the charge in the point $R_k$ in the time moment $t$ through $Z_k$. The charge $Z_k$ is the total proton charge $X_k$ of the nucleus (initial proton charge of splinter + proton charge of $\beta$-fission products) and electron charge $Y_k$ of $\beta$-fission products:

$$Z_k = X_k + Y_k.$$  

(8)

Obviously, value $Z_k$ (8) coincides with charged value of initial proton charge of splinter. Nevertheless, it is necessary to make use of expansion (8) for account of radioactive fission effect of the nucleus of $k$-th splinter.

Further we shall think that solutions $E_0$ and $B_0$ of field equations can be approximated as converged rows on parameter $|r_k|/|R_k - R| < 1$, i.e. the dimensions of a splinter $R_k$ is smaller a distance $\sigma_k$ from the observation point $R$ to fixed point (nucleus) $R_k$ of $k$-th splinter. Transform equations (1) taking into account of all expansions including the $\delta$-function expansion into the Taylor’s row on $r_k$ in the locality of the point $(R_k - R)$. Then we obtain

$$\nabla E_0 = \frac{1}{c^2} \sum_k Z_k \sum_{n=0}^\infty \frac{(-1)^n}{n!} (r_k \nabla)^n \delta(R_k - R)$$

$$+ \sum_k X_k \delta(R_k - R) + \sum_k Y_k \delta(R_k - R),$$

$$-E'_0 + \nabla \times B_0 = \frac{1}{c^2} \sum_k Z_k \sum_{n=0}^\infty \frac{(-1)^n}{n!} (r_k \nabla)^n \delta(R_k - R)$$

$$+ \frac{1}{c} \sum_k X_k \dot{R}_k \delta(R_k - R) + \frac{1}{c} \sum_k Y_k \dot{R}_k \delta(R_k - R),$$

$$\nabla B_0 = 0, \quad B'_0 + \nabla \times E_0 = 0.$$  

(9)

In equations of system (9) we have operator equality of action to three-dimensional $\delta$-function:

$$\nabla_k \delta(R_k - R) = -\nabla \delta(R_k - R),$$

where $\nabla_k = \partial / \partial R_k$, $\nabla = \partial / \partial R$. Consider this system in detail. The first
equation can be written in the shortened form:

$$\nabla E_s = q - \nabla p + s_+ + s_-,$$

(10)

where is denoted

$$q = \sum_k q_k, \quad q_k = \sum_i Z_{ui} \delta(R_k - R),$$

(11)

$$p = \sum_k p_k, \quad p_k = \sum_i \sum_{\nu=0}^{\infty} \left(-\frac{1}{\nu!}\right) r_{\nu} (r_{\nu} \nabla)^{\nu-1} \delta(R_k - R),$$

(12)

$$s_+ = \sum_k X_k \delta(R_k - R), \quad s_- = \sum_k Y_k \delta(R_k - R).$$

(13)

Then we transpose the second equation of system (9) to the form

$$-E_s' + \nabla \times B_s = \frac{1}{c} \left[ j - \sum_k \hat{R}_k \nabla p_k + \sum_k \sum_i Z_{ui} \sum_{\nu=0}^{\infty} \left(-\frac{1}{\nu!}\right) \hat{r}_{\nu} (r_{\nu} \nabla)^{\nu-1} \delta(R_k - R) + \sum_k X_k \hat{R}_k \delta(R_k - R) \right],$$

(14)

where is denoted

$$j = \sum_k j_k, \quad j_k = \sum_i Z_{ui} \hat{R}_k \delta(R_k - R).$$

(15)

Further we make use of operator equality of action to the \(\delta\)-function:

$$\frac{\partial}{\partial t} \delta(R_k - R) = -\hat{R}_k \nabla \delta(R_k - R).$$

(16)

Differentiate the relation (12) on \(\partial/\partial (ct)\):

$$p_k' = \frac{1}{c} \hat{R}_k \nabla p_k + \frac{1}{c} \sum_i Z_{ui} \sum_{\nu=0}^{\infty} \left(-\frac{1}{\nu!}\right) \hat{r}_{\nu} (r_{\nu} \nabla)^{\nu-1} \delta(R_k - R) = 0.$$ (17)

Then we add up relation (17) by \(k\) and add to right part of Equation (14). The second equation of field (14) with aid of vector identity \(\nabla \times (a \times b) = (\nabla b) a - (\nabla a) b\) justifiable for any vectors \(a\) and \(b\) can be written in the form

$$-E_s' + \nabla \times B_s = \frac{1}{c} j + \frac{1}{c} p' + \nabla \times m + \frac{1}{c} (u_+ + u_-),$$

(18)

where following designations are introduced

$$m = \sum_k m_k, \quad m_k = \frac{1}{c} \left[ p_k \times \hat{R}_k + \sum_i Z_{ui} \sum_{\nu=0}^{\infty} \left(-\frac{1}{\nu!}\right) \hat{r}_{\nu} (r_{\nu} \nabla)^{\nu-1} \delta(R_k - R) \right],$$

(19)

$$u_+ = \sum_k X_k \hat{R}_k \delta(R_k - R), \quad u_- = \sum_k Y_k \hat{R}_k \delta(R_k - R).$$

(20)

Here the vector \(m\) uses the name of magnetic vector.

Note that in Equations (10), (18) summands \(s_+ c^{-1} u_+\) and \(s_- c^{-1} u_-\) (13), (20) can be associated with outrunning and retarding fields in relativistic and plus- and minus-fields in quantum electrodynamics [2] [15] [16] [17] [18].

Values \(s_+ c^{-1} u_+\) represent own fields of the charged nucleuses of all splinters and \(s_- c^{-1} u_-\) represent “the deformation” of total field is caused by the effect of radioactive \(\beta\)-fission of nucleuses of all splinters.

We consider full charge of the \(k\)-th splinter
\[ \zeta_k = \sum_{j} Z_{uj} + Z_k = \sum_{i} Z_{ui} + X_k + Y_k. \]  

(21)

Taking into account designation (21) for fission-fragment charge and expressions (11) and (15) can be written that

\[ Q = q + s_+ + s_- = \sum_{k} \zeta_k \delta(R_k - R), \]
\[ J = j + u_+ + u_- = \sum_{k} \zeta_k \dot{R}_k \delta(R_k - R). \]  

(22)

Values \( Q \) and \( J \) are determined by equalities (22) on the analogy of electrodynamical standards may call densities of the fission-fragment charge and current correspondingly.

It is easy to notice that from system (22) conservation law of the fission-fragment charge follows directly:

\[ \frac{\partial Q}{\partial t} = - \nabla J. \]  

(23)

Indeed, formula (23) follows if the value \( \frac{\partial Q}{\partial t} \) from the first relation of system (22) to calculate with the aid of equality (16) and then to make use of the second relation of system (22).

Values \( p \) (12) and \( m \) (19) in conformity with accepted electrodynamical standards can be named the fission-fragment electric and magnetic polarizable densities.

Thus, the system of equations for the field of charged fission splinters into terms of densities of charge, current, electric and magnetic polarization looks as:

\[ \nabla E = Q - \nabla p, \]

\[ -E'_k + \nabla \times B_k = \frac{1}{c} J + p' + \nabla \times m, \]

\[ \nabla B = 0, \quad B'_k + \nabla \times E_k = 0. \]  

(24)

The system of Equation (24) are the system of microscopic fields \((E_k, B_k)\) induced by splinters. In other words, these fields where fission splinters are situated. Notice simultaneously that on own form these fields are quite identical to the Maxwell macroscopic field equations for continuous medium. Equation (24) can be named equations of the fission-fragment fields. If introduce instead of vectors \( p \) and \( m \) vectors of displacement \( D \) and \( H \) correspondingly to formulas

\[ D_k = E_k + p, \quad H_k = B_k - m, \]

then obviously that the system of equations of fission-fragment fields (24) assumes the form (compare with the system of the Maxwell macroscopic equations for variable electromagnetic field \((E, D, H, B)\): \( \text{rot} E = - \frac{\partial B}{\partial t}, \)

\( \text{div} D = \rho, \quad \text{rot} H = j + \frac{\partial D}{\partial t}, \quad \text{div} B = 0, \) where \( j + \frac{\partial D}{\partial t} \) is the density of the full current, \( j \) is the density of the conductivity current, \( \rho \) is the volumetric charged density, \( I = \int_S j \, dS \) is the conductivity current, \( I_s = (d/dt) \int_S D \, dS \) is the displacement current, \( S \) is the surface):

\[ \nabla D = Q, \quad -D'_k + \nabla \times H_k = \frac{1}{c} J, \]
\[ \nabla B = 0, \quad B' + \nabla \times E = 0. \]  

(25)

We now move on to formation of equations for dynamics of charged fission splinters if there are given off electrons arised as a result of radioactive \( \beta^- \)-disintegration.

The motion equation of \( ki \)-th particle into \( k \)-th splinter with the charge \( Z_{ik} \), the mass \( m_{ik} \) and the coordinate \( R_{ik} \) at the time moment \( t \) into full electromagnetic field \( (E(R_{ik},t), B(R_{ik},t)) \) has a form of Equation (6), where \( R_i \rightarrow R_{ik} \), i.e.

\[
m_{ik} \ddot{R}_{ik} = Z_{ik} \left[ E(R_{ik},t) + \frac{1}{c} \dot{R}_{ik} \times B(R_{ik},t) \right],
\]

(26)

moreover full fields \( E(R_{ik},t) \) and \( B(R_{ik},t) \) in considered case (compare with expressions for \( E \) and \( B \) in Equation (7)) have a form

\[
E(R_{ik},t) = -\sum_j \nabla_{ik} \frac{Z_{ij}}{4\pi \sigma_{sl,ij}} - \nabla_{ik} \frac{(X_k + Y_k)}{4\pi \sigma_{s,k}} - \sum_j \nabla_{ik} \frac{Z_{ij}}{4\pi \sigma_{sl,ij}} - \sum_j \nabla_{ik} \left( \frac{X_j + Y_j}{4\pi \sigma_{sl,j}} + E_0(R_{ik},t) \right),
\]

(27)

\[
B(R_{ik},t) = B_0(R_{ik},t),
\]

where \( j \neq i, l \neq k \); \( \nabla_{ik} \)—is the gradient vector on the elements of vector \( R_{ik} \).

In the system of Equation (27) are denoted

\[
\sigma_{s,j} = |R_j - R_k|, \quad \sigma_{s,i} = |R_i - R_k| = |R_i - R_i|,
\]

\[
\sigma_{sl,j} = |R_{ik} - R_j|, \quad \sigma_{sl,i} = |R_{ik} - R_i| = |R_i - R_i|,
\]

\[
R_{ik} = R_k, \quad R_{ij} = R_i, \quad |R_i - R_i| = |r_i|.
\]

(28)

One can see beautifully from relations (27) that full field \( (E, B) \) includes:

1) intrafission-fragment field created by all particles \( ki, i \neq j \), of given \( k \)-th splinter and by nucleus of this splinter;

2) interfission-fragment fields corresponding to particles of all other \( l \) splinters, \( l \neq k \), and to nucleuses of these splinters also;

3) external field \( (E_0, B_0) \) created by external sources.

On the analogy of (6) \((i \rightarrow k)\) can be written the motion equation of the nucleus of \( k \)-th splinter with charge \( Z_k = X_k + Y_k \), mass \( m_k \), coordinate \( R_k \) into full electromagnetic field \( (E(R_k,t), B(R_k,t)) \):

\[
m_k \ddot{R}_k = Z_k \left[ E(R_k,t) + \frac{1}{c} \dot{R}_k \times B(R_k,t) \right],
\]

(29)

where

\[
E(R_k,t) = -\sum_j \nabla_{k} \frac{Z_{kj}}{4\pi \sigma_{sk,j}} - \sum_j \nabla_{k} \frac{Z_{kj}}{4\pi \sigma_{sl,kj}} - \sum_j \nabla_{k} \left( \frac{X_j + Y_j}{4\pi \sigma_{sl,j}} + E_0(R_k,t) \right),
\]

(30)

\[
B(R_k,t) = B_0(R_k,t),
\]

for \( l \neq k \), i.e. system of relations (29), (30) can be obtained from system (26),
After summarizing of Equation (26) on $i$ and adding with Equation (29) for description of the motion of $k$-th splinter with mass $m_k$ and coordinate of masses center $R_k$:

$$\ddot{m}_k = \sum_{i} + m_k, \quad \ddot{R}_k = \sum_{i} \frac{m_k R_{ki} + m_i R_k}{m_k},$$

we obtain the motion equation of $k$-th splinter in the form

$$\ddot{m}_k \dddot{R}_k = -\sum_{i} \sum_{j} \nabla \left[ Z_{ki} Z_{kj} \frac{Z_{ij} X_i + Y_j}{4\pi \sigma_{kij}} \right] - \sum_{i} \sum_{j} \nabla \left[ Z_{ki} X_i Y_j \right] + \sum_{i} \sum_{j} \nabla \left[ Z_{ij} X_i Y_j \right]$$

$$\left( \frac{X_k + Y_k}{4\pi \sigma_{kkl}} \right)$$

$$\left( \frac{X_k + Y_k}{4\pi \sigma_{kkl}} \right) - \sum_{i} \nabla \left[ E_0 (R_{ki}, t) + \frac{1}{c} \dot{R}_k \times B_0 (R_{ki}, t) \right]$$

$$+ \left( \frac{X_k + Y_k}{4\pi \sigma_{kkl}} \right) \left[ E_0 (R_k, t) + \frac{1}{c} \dot{R}_k \times B_0 (R_k, t) \right],$$

where $i \neq k$, and external field $(E_0, B_0)$ satisfies to homogeneous equations

$$\nabla B_0 = 0, \quad B_0' + \nabla \times E_0 = 0.$$

Thus, Equation (32) is the motion equation of $k$-th splinter into electromagnetic field of other splinters and external sources.

It is important to note that Equation (32) on a level with traditional summands in the right part of the Lorenz force contains also summands are made a force connected with radioactive charged radiation of nucleuses into fission splinters (the accounting of $\beta^-$ charged radiation by the radioactive electrodynamic effect).

In following section will be realized the breeding of “the energy equation” for fission splinters with charged radioactivity, namely the equation in conformity with it total derivative on the time from energy of system is equal to short-active and long-active contributions containing the powerful components of different forces.

4. Power Relations for the Charged Fission Splinters

Proceed to the substantiation of energy equation and internal pulse moment of $k$-th splinter on the basis of previous section results.

For working out of energy equation we take $ki$-th particle and scalarly multiply motion Equation (26) by velocity $\dot{R}_{ki}$:
Similarly we treat with the nucleus of \( k \)-th splinter. From Equation (29) after multiply by the vector \( \vec{R}_k \) we have

\[
m_i \dot{R}_i \dot{R}_i = Z_i \dot{R}_i E(R_i, t).
\]

Then summarise by \( i \) Equation (33) and add with Equation (34). With the aid of expressions for \( \vec{m}_k \) and of relations (27), (30) we find for internal coordinate \( \tau_{ki} = R_{ki} - \vec{R}_k \) that

\[
\frac{d}{dt} \left( \frac{1}{2} \sum_i m_i \dot{R}_i^2 + \frac{1}{2} m_k \dot{R}_k^2 + \frac{1}{2} \dot{m}_k \left( \vec{R}_k - \vec{R}_k^2 \right) \right)
= \sum_i Z_i \dot{R}_i E(R_i, t) + Z_k \dot{R}_k E(R_k, t),
\]

or

\[
\frac{d}{dt} \left( \frac{1}{2} \sum_i m_i \dot{\vec{R}}_i^2 + \sum_i m_i \dot{\vec{R}}_i + \frac{1}{2} \dot{m}_k \vec{R}_k^2 + \frac{1}{2} m_k \left( \vec{R}_k^2 - \vec{R}_k^2 \right) \right)
= \sum_i \dot{R}_i \nabla \cdot \left( \frac{Z_i Z_i}{4\pi \sigma_{k,j}} \nabla \cdot \left( \frac{Z_i Z_i}{4\pi \sigma_{k,j}} \right) - \frac{Z_k (X_i + Y_i)}{4\pi \sigma_{k,j}} \right)
\]

\[
+ \sum_j \dot{R}_j Z_j E_0 (R_j, t) - \sum_j \dot{R}_j \nabla \cdot \left( \frac{Z_j Z_j}{4\pi \sigma_{k,j}} \right) - \sum_k \dot{R}_k \nabla \cdot \left( \frac{Z_k (X_k + Y_k)}{4\pi \sigma_{k,j}} \right)
\]

\[
- \sum_j \dot{R}_j \nabla \cdot \left( \frac{X_k + Y_k (X_k + Y_k)}{4\pi \sigma_{k,j}} \right) + \dot{R}_k (X_k + Y_k) E_0 (R_k, t),
\]

where \( i \neq j, l \neq k \).

In right part of Equation (35) the first, the second and the sixth summands are making intrafission-fragment power contribution which can be presented as a total derivative on the time from intrafission-fragment Coulomb's energy of given \( k \)-th splinter \( E_{C,k} \):

\[
- \sum_{i,j} \dot{R}_j \nabla \cdot \left( \frac{Z_i Z_j}{4\pi \sigma_{k,j}} \right) - \sum_{i,j} \dot{R}_j \nabla \cdot \left( \frac{Z_i Z_j}{4\pi \sigma_{k,j}} \right) - \sum_k \dot{R}_k \nabla \cdot \left( \frac{Z_k (X_k + Y_k)}{4\pi \sigma_{k,j}} \right)
\]

\[
= - \sum_{i,j} \left( \dot{R}_k \nabla \cdot \left( \frac{Z_i Z_j}{8\pi \sigma_{k,j}} \right) + \dot{R}_j \nabla \cdot \left( \frac{Z_i Z_j}{8\pi \sigma_{k,j}} \right) \right) - \sum_j \left( \dot{R}_k \nabla \cdot \left( \frac{Z_k (X_k + Y_k)}{8\pi \sigma_{k,j}} \right) \right)
\]

\[
= \frac{d}{dt} E_{C,k},
\]

or

\[
\frac{d}{dt} E_{C,k} = \frac{d}{dt} \frac{1}{8\pi} \left( \sum_{i,j} \frac{Z_i Z_j}{|\vec{R}_i - \vec{R}_j|} + \sum_i \frac{Z_i Z_k}{|\vec{R}_i + \vec{R}_k - \vec{R}_k|} + \sum_j \frac{Z_j Z_k}{|\vec{R}_j + \vec{R}_k - \vec{R}_k|} \right). \tag{36}
\]

In general case Equation (35) taking into account the dependence (36) can be produced in the form
\[
\frac{d}{dt} \left( \frac{1}{2} \sum_i m_i \dot{\mathbf{r}}^2_i + \sum_i m_i \mathbf{R}_i \cdot \dot{\mathbf{R}}_i + \frac{1}{2} m_i \mathbf{\ddot{r}}^2_i + \frac{1}{2} m_i \left( \mathbf{\ddot{R}}_i - \mathbf{\ddot{R}}_k \right) + E_{C,k} \right) = \Lambda_{k,j} + \Lambda_{k,0},
\]

where is denoted

\[
\Lambda_{k,j} = \sum_{l,j} \left( \mathbf{\ddot{R}}_l + \mathbf{\ddot{r}}_l \right) \nabla_{l,j} \frac{Z_u Z_j}{4\pi \sigma_{u,j}} - \sum_{l,j} \left( \mathbf{\ddot{R}}_l + \mathbf{\ddot{r}}_l \right) \nabla_{l,j} \frac{Z_u (X_i + Y_j)}{4\pi \sigma_{u,j}}
- \sum_l \mathbf{\ddot{R}}_l \nabla_{l} \frac{(X_i + Y_j) Z_u}{4\pi \sigma_{u,l}} - \sum_l \mathbf{\ddot{R}}_l \nabla_{l} \frac{(X_i + Y_j) (X_i + Y_j)}{4\pi \sigma_{u,l}},
\]

\[
\Lambda_{k,0} = \sum_l \left( \mathbf{\ddot{R}}_l + \mathbf{\ddot{r}}_l \right) Z_u E_0 (R_{u_i}, t) + \mathbf{\ddot{R}}_l (X_i + Y_j) E_0 (R_{u_i}, t).
\]

Thus, the energy equation of \( k \)-th splinter (37) in own left part contains summands of intrafission-fragment kinetic, potential and Coulomb's energies; quantities determining interfission-fragment, \( \Lambda_{k,j} \) and external \( \Lambda_{k,0} \) fields on the background of \( \beta^- \)-charged radiation were in the right part of this equation.

For working out of internal pulse moment equation of \( k \)-th splinter we make use of corresponding expression for the quantity of internal pulse moment

\[
\Psi_k = \sum_i m_i \mathbf{\ddot{r}}_i \times \mathbf{\ddot{r}}_i + m_k \left( R_k - \mathbf{\ddot{R}}_k \right) \times \left( \mathbf{\ddot{R}}_k - \mathbf{\ddot{R}}_i \right),
\]

where \( m_i, m_k \) are masses of composed particles and nucleus of \( k \)-th splinter, \( \mathbf{\ddot{r}}_i = R_{u_i} - \mathbf{\ddot{R}}_i \) are internal coordinates of particles.

Differentiate relation (38) on the time. Then we obtain with employment of significances of \( \mathbf{\ddot{R}}_k, \mathbf{\ddot{R}}_i \):

\[
\Psi_k = \sum_i m_i \mathbf{\ddot{r}}_i \times \mathbf{\ddot{r}}_i + m_k \left( R_k - \mathbf{\ddot{R}}_k \right) \times \left( \mathbf{\ddot{R}}_k - \mathbf{\ddot{R}}_i \right)
- \sum_i m_i \mathbf{\ddot{r}}_i \times \mathbf{\ddot{r}}_i + m_k \left( R_k - \mathbf{\ddot{R}}_k \right) \times \left( \mathbf{\ddot{R}}_k - \mathbf{\ddot{R}}_i \right)
= \sum_i m_i \mathbf{\ddot{r}}_i \times \mathbf{\ddot{r}}_i + m_k \left( R_k - \mathbf{\ddot{R}}_k \right) \times \mathbf{\ddot{R}}_i. \tag{39}
\]

The following step: put motion Equations ((26), (29)) and equations of fields (27), (30) into Equation (39). We obtain finally

\[
\Psi_k = -\sum_{i,l,j} \mathbf{\ddot{r}}_i \times \mathbf{\ddot{r}}_j \frac{Z_u Z_j}{4\pi \sigma_{u,j}} - \sum_{i,l,j} \mathbf{\ddot{r}}_l \times \mathbf{\ddot{r}}_j \frac{Z_u (X_i + Y_j)}{4\pi \sigma_{u,j}}
+ \sum_l Z_u \mathbf{\ddot{r}}_l \times \left[ E_0 (R_{u_i}, t) + \frac{1}{c} \mathbf{\ddot{R}}_u (R_{u_i}, t) \right]
- \sum_l \left( R_k - \mathbf{\ddot{R}}_k \right) \times \mathbf{\ddot{r}}_l \frac{(X_i + Y_j) Z_u}{4\pi \sigma_{u,l}}
- \sum_l \left( R_k - \mathbf{\ddot{R}}_k \right) \times \mathbf{\ddot{r}}_l \frac{(X_i + Y_j) (X_i + Y_j)}{4\pi \sigma_{u,l}}
+ \left( X_i + Y_j \right) \left( R_k - \mathbf{\ddot{R}}_k \right) \times \left[ E_0 (R_k, t) + \frac{1}{c} \mathbf{\ddot{R}}_u (R_k, t) \right],
\]

where \( i \neq j, l \neq k \) and resulting activity of central forces corresponding intrafission-fragment fields is equal zero.
5. Statistical Description of Nonrelativistic Nuclear Electrodynamics Laws

Maxwell’s equations of electromagnetic field are in reality macroscopic equations for the description of field and substance with slowly-varying (into time and space) physical variables. Consequently their employment for the description of microscopic objects behaviour with quickly-varying physical variables cannot be recognized fully adequate and theoretically correct.

Macroscopic equations operate with not separate particle but with whole group of particles (medium). Obviously from this point of view that for the obtaining of nuclear electromagnetic macroscopic laws it is necessary to carry out averaging on fission splinters and to avail of statistical mechanics principles where physical variables describing with the aid of distribution functions are considered as continuous functions of spatio-temporal coordinates.

We note also for the carrying-out of statistical (macroscopic) physics it is necessary that averaging on considered splinters occured in the volume with sizes bigger than interfission-fragment distances but smaller than macroscopic sizes of the system.

Statistical averaging in statistical mechanics is introduced with the aid of distribution function or phase density $f(x)$ in phase space where $x(t)$ is phase vector of the system [19] [20].

In nonrelativistic case macroscopic values can be averaged only on phase space of coordinates and velocities of particles. Therefore, if $k_i$-th particle is characterized by microscopic value $a(R_{k_i}, R_{k_i}, t)$ then the average from it is defined by this integral

$$\langle a \rangle = \int \mathcal{A} d\varphi,$$

where $\mathcal{A} = f(R_{k_i}, R_{k_i}, t)$ is distribution function, $d\varphi = \prod_{k_i} dR_{k_i} dR_{k_i}$ is a element of the phase space volume, $f d\varphi$ is the probability of system stay in the element of volume $d\varphi$ (owing to the conservation of probability $f d\varphi = \text{const}$ along phase trajectory).

Hence it follows the commutation of operations of the differentiation on the time and the averaging on phase space and spatial differentiation and phase averaging also:

$$\frac{\partial}{\partial t} \langle a \rangle = \int \frac{d}{dt} f d\varphi = \int f \frac{d}{dt} d\varphi = \left( \langle \frac{da}{dt} \rangle \right),$$

$$\nabla \langle a \rangle = \nabla \int af d\varphi = \int \nabla af d\varphi = \langle \nabla a \rangle,$$

where

$$\frac{d}{dt} = \frac{\partial}{\partial t} + \sum_{k_i} \dot{R}_{k_i} \nabla_{k_i} + \sum_{k_i} \ddot{R}_{k_i} \nabla_{k_i},$$

$$\nabla_{k_i} = \frac{\partial}{\partial R_{k_i}}, \quad \nabla_{k_i} = \frac{\partial}{\partial R_{k_i}}.$$

So that to receive Maxwell’s equations it is necessary to apply statistical averaging to equations of fission-fragment fields (24). Then we shall be having
\[ \langle \nabla E_\ast \rangle = \langle Q \rangle - \langle \nabla p \rangle, \]
\[ -\langle E_\ast' \rangle + \langle \nabla \times B_\ast \rangle = \frac{1}{c} \langle J \rangle + \langle p' \rangle + \langle \nabla \times m \rangle, \]
\[ \langle \nabla B_\ast \rangle = 0, \quad \langle B_\ast' \rangle + \langle \nabla \times E_\ast \rangle = 0, \]
\[(42)\]

and further, with the aid of commutation rule (41) in system of Equation (42) we obtain
\[ \nabla \langle E_\ast \rangle = \langle Q \rangle - \nabla \langle p \rangle, \]
\[ -\langle E_\ast' \rangle + \nabla \times \langle B_\ast \rangle = \frac{1}{c} \langle J \rangle + \langle p' \rangle + \nabla \times \langle m \rangle, \]
\[ \nabla \langle B_\ast \rangle = 0, \quad \langle B_\ast' \rangle + \nabla \times \langle E_\ast \rangle = 0. \]
\[(43)\]

Use designation (40) for macroscopic fields, densities of charge, current and vectors of polarizations
\[ \mathcal{E} = \langle E_\ast \rangle, \quad \mathcal{B} = \langle B_\ast \rangle, \quad \mathcal{Q} = \langle Q \rangle, \quad \mathcal{J} = \langle J \rangle, \]
\[ \mathcal{P} = \langle p \rangle, \quad \mathcal{M} = \langle m \rangle. \]

Then we can rewrite system (43) in the form of Maxwell’s equations:
\[ \nabla \mathcal{E} = \mathcal{Q} - \nabla \mathcal{P}, \]
\[ -\mathcal{E}' + \nabla \times \mathcal{B} = \frac{1}{c} \mathcal{J} + \mathcal{P}' + \nabla \times \mathcal{M}, \]
\[ \nabla \mathcal{B} = 0, \quad \mathcal{B}' + \nabla \times \mathcal{E} = 0. \]
\[(44)\]

If resort to designations for vectors of displacement
\[ (\mathcal{D} = \mathcal{E} + \mathcal{P}, \mathcal{H} = \mathcal{B} - \mathcal{M}), \]

the system of Maxwell’s Equation (44) can be written in still more compact form:
\[ \nabla \mathcal{D} = \mathcal{Q}, \quad -\mathcal{D}' + \nabla \times \mathcal{H} = \frac{1}{c} \mathcal{J}, \]
\[ \nabla \mathcal{B} = 0, \quad \mathcal{B}' + \nabla \times \mathcal{E} = 0. \]
\[(45)\]

System of Equation (45) can be obtained by means of the averaging of system (25) also. We note that system of Equation (45) into known terms of Maxwell fields \( \mathcal{E}, \mathcal{B}, \mathcal{D} \) and \( \mathcal{H} \) is comfortable for the employment in the case of assignment of some boundary conditions.

Continue the derivation of macroscopic equations on the basis of the averaging of microscopic equations. Then analogously by means of the averaging of Equation (23) can obtain macroscopic equation of the charge conservation
\[ \frac{\partial \mathcal{Q}}{\partial t} = -\nabla \mathcal{J}. \]
\[(46)\]

If further to average relations (22) then we find macroscopic densities of charge and current correspondingly:
\[ \mathcal{Q}(R,t) = \langle Q \rangle = \left( \sum_k \xi_k \delta(R_k - R) \right), \]
Write solutions of macroscopic Equation (44) to an approximation of summands in order 1/c:

$$J(R,t) = \langle J \rangle = \left\{ \sum_{i} \xi_i \hat{R}_i \delta \left( \hat{R}_i - R \right) \right\}.$$ 

Field equations into terms of Hermite's operators of electric and magnetic fields have the form

$$\nabla \hat{E} = \sum_{i} Z_i \delta \left( \hat{R}_i - R \right),$$

$$-\hat{E}' + \nabla \times \hat{B} = \frac{1}{2c} \sum_{i} \left\{ \hat{R}_i, \delta \left( \hat{R}_i - R \right) \right\},$$

$$\nabla \hat{B} = 0, \quad \hat{B}' + \nabla \times \hat{E} = 0,$$

where in the second equation of system (49) in right part is the anti-commutator providing the hermicity of sources in field equations and what’s more the relation

$$\dot{A} = c \dot{A}' = \frac{i}{\hbar} \left[ \hat{H}, \hat{A} \right] + \frac{\partial \hat{A}}{\partial t}.$$
has place for the operator $\hat{A}$. In equality (50) $\partial \hat{A} / \partial t$ means the open derivative on the time, i.e. we assume that the operator $\hat{A}$ depends from the time obviously. Specifically, if in expression (50) the operator $\hat{A}$ don’t depends from the time obviously then we have known as Heisenberg’s motion equation for operators which are independent from the time obviously [21] [22]:

$$\frac{d\hat{A}(t)}{dt} = \frac{i}{\hbar} [\hat{H}(t), \hat{A}(t)].$$

(51)

Since Equation (51) has open similarity with corresponding equation of classical mechanics of Poisson’s brackets then the commutator in the right part of Equations ((50), (51)) is named quantum brackets of Poisson from $\hat{H}$ and $\hat{A}$ also. We remind that commutator by two operators is named the moved form $[A,B] = AB - BA$. We note also that $\hat{R} = \hat{P}_x / m$ follows from expression (47) with an approximation of summands in order $c^0$.

So that to write motion equation for charged $i$-th particle it is necessary by the calculation of derivatives on the time from $\hat{R}$ to take advantage of rule (50). Then with the aid of expression for $\hat{H}$ (47) we obtain

$$m_i \ddot{\hat{R}}_i = \ddot{\hat{P}}_i - \frac{1}{c} Z_i A_0 \left( \hat{R}_i, t \right),$$

$$m_i \dddot{\hat{R}}_i = -\dddot{\hat{V}}_i \sum_j \frac{Z_i Z_j}{4\pi \sigma_{ij}} + Z_i \left[ E_0 \left( \hat{R}_i, t \right) + \frac{1}{2c} \left\{ \frac{\hat{P}_i}{m_i} B_0 \left( \hat{R}_i, t \right) \right\} \right],$$

(52)

where $\dddot{\hat{V}}_i = \partial \hat{V}_i / \partial \hat{R}_i, i \neq j$. Here external field $(E_0, B_0)$ is connected with scalar and vector potentials $(\phi_0, A_0)$ by dependences (2), (3) so that

$$E_0 = -\nabla \phi_0 - A_0', \quad B_0 = \nabla \times A_0,$$

moreover in the right part of Equation (52) over the $\{ A, B \}^\ast$ is indicated rearranged form with vector product: $\{ A, B \}^\ast = A \times B - B \times A$.

In conclusion we adduce quantumomechanical description of microscopic field equations of charged fission splinters (24) for average values of corresponding operators. The system in Hilbert’s space is described by the state vector $\psi(t)$ or Hermite’s operator of the density $\hat{\Psi}(t) = \psi(t) \psi^\ast(t)$. Average values $\overline{A}$ of the operator $\hat{A}$ is introduced as

$$\overline{A} = \psi^\ast \hat{A} \psi \text{ or } \overline{A} = \text{Sp} \left( \hat{\Psi} \hat{A} \right).$$

Formally for notes of fields equations of fission splinters it is necessary demand the performance of the condition $|r_{ij}| = |R_{ij} - R_i| < |R_{i} - R|$ which guarantees the participation of those observation points $R$ situated out of splinters and which provides the convergence of the row expansion (in this case the row converges for sources).

We have for average values of operators (compare with system (24)):

$$\nabla \overline{E} = \overline{Q} - \nabla \overline{P},$$

$$-\overline{E}' + \nabla \times \overline{B} = \frac{1}{c} \overline{J} + \overline{P}' + \nabla \times \overline{m}.$$
\[ \nabla B = 0, \quad \vec{B}' + \nabla \times \vec{E} = 0, \] 

(53)

where operators are determined by expressions

\[ \hat{Q} = \sum_\kappa \zeta_\kappa \delta \left( \hat{R}_\kappa - \hat{R} \right), \]

\[ \hat{J} = \frac{1}{2} \sum_\kappa \zeta_\kappa \left[ \hat{v}_\kappa, \delta \left( \hat{R}_\kappa - \hat{R} \right) \right], \quad \hat{v}_\kappa = i \hbar \left[ \hat{H}, \hat{R}_\kappa \right], \]

(54)

and the anti-commutator and the commutator for velocity operator are in the second and the third relations (54) correspondingly.

Motion equation of \( ki \)-th particle in \( k \)-th splinter has the form of operator equation:

\[ m_i \hat{R}_i = Z_i \left[ \hat{E} \left( \hat{R}_i, t \right) + \frac{1}{2c} \left\{ \hat{P}_i, m_i, B_0 \left( \hat{R}_i, t \right) \right\} \right], \]

(55)

where

\[ \hat{E} \left( \hat{R}_i, t \right) = \frac{1}{4\pi} \hat{\nabla}_i \left[ - \sum_j Z_j \hat{\sigma}_{kj,j} - \left( X_k + Y_k \right) \hat{\sigma}_{k,kl} - \sum_l Z_l \hat{\sigma}_{kl,ll} \right. \]

\[ \left. - \sum_l \left( X_l + Y_l \right) \hat{\sigma}_{il,ll} \right] + F_0 \left( \hat{R}_i, t \right), \]

\[ \hat{B} \left( \hat{R}_i, t \right) = B_0 \left( \hat{R}_i, t \right); \quad j \neq i, \quad l \neq k, \quad \hat{\nabla}_i = \frac{\partial}{\partial \hat{R}_i}. \]

Here the designation \( \hat{\sigma} \) indicates only on the presence of coordinates operator \( \hat{R} \) with corresponding indexes.

Analogously the motion equation of nucleus of \( k \)-th splinter can be written in the operator form:

\[ m_k \hat{R}_k = Z_k \left[ \hat{E} \left( \hat{R}_k, t \right) + \frac{1}{2c} \left\{ \hat{P}_k, m_k, B_0 \left( \hat{R}_k, t \right) \right\} \right], \]

(56)

where

\[ \hat{E} \left( \hat{R}_k, t \right) = \frac{1}{4\pi} \hat{\nabla}_k \left[ - \sum_j Z_j \hat{\sigma}_{kj,j} - \sum_l \sum_j Z_l \hat{\sigma}_{ll,j} - \sum_l \left( X_l + Y_l \right) \hat{\sigma}_{li,ll} \right. \]

\[ \left. + F_0 \left( \hat{R}_k, t \right), \right. \]

\[ \hat{B} \left( \hat{R}_k, t \right) = B_0 \left( \hat{R}_k, t \right). \]

Summation of motion equations of particles (55) and addition their with motion equation of nucleus (56) as a result led to a motion equation of the masses center of \( k \)-th splinter.

Field Equations ((49), (53)) and motion equations of charged particles and fission splinters (52), (55), (56) form the base for further deduction of operator macroscopic field equations and motion equations into quantumomechanical interpretation taking into account \( \beta \)-charged radioactive radiation.

**7. Conclusion**

Here in essence the nuclear electrodynamics theory is presented. This theory opens wide perspectives for the creation of power devices in the form of the
nuclear electrogenerator which functions on new principles of the passing of nuclear fission reaction into directional electromagnetic fields. Chain fission of heavy nuclei is one of many physical phenomena which proceed in an avalanche scheme. In fission there is an impetuous increase in the numbers of neutrons, charged particles and fission splinters with enormous kinetic energy. The present theory aims to describe the above process quantitatively. In the future it could find an application in powerful nuclear electrogenerators operating exclusively on the basis of electronuclear conversions.
