Abstract

In this paper, we want to make a new type linear piezoelectric motor by mode shape coating or effective electrode surface coating. The mode shape is derived from the mechanical boundary conditions of the linear piezoelectric motor. We only have access to the first three modes of formas, the effective electrode surface coating basis, as well as with the linear piezoelectric motor of normal shape do comparison. Next, we will inspect their gain or axial velocity through theoretical analysis, simulation and experiment. According to the results of the theoretical analysis, we have found that the gain or axial velocity of the linear piezoelectric motors of mode shape is much larger than the linear piezoelectric motors of normal shape. However, according to the results of simulation and experiments, we have found that the gain or axial velocity of the linear piezoelectric motors of mode shape is much greater than the linear piezoelectric motors of normal shape, which is about 1.2 to 1.4 times. The linear piezoelectric motor of mode shape 3 has the fastest axial velocity, which is about $-48 \text{ mm/s}$ and $48 \text{ mm/s}$ under conditions of $180 V_{p-p}$ driving voltage, $21.2 \text{ kHz}$ driving frequency (the third vibration modal), $25 \text{ gw}$ loading and the position of loading or mass at $x = 5 \text{ mm} & 45 \text{ mm}$ respectively. And its axial velocity is about 1.4 times the linear piezoelectric motor of normal shape under the same conditions. Overall, the mode shape coating helps to enhance the gain or axial velocity of the linear piezoelectric motor.

Keywords

Linear Piezoelectric Motor (LPM), Mode Shape (MS), Normal Shape (NS), Gain, Axial Velocity

1. Introduction

Over the past decade, the linear piezoelectric motors have a very significant development and excellent performance, as shown in Table 1 [1]-[19]. If we do not consider the size and the driving condition of the piezoelectric linear motors, their linear moving fastest is a high-power linear ultrasonic motor using bending vibration.
Table 1. The performance comparison of the linear piezoelectric motors [1]-[19].

transducer [15], the ultrasonic linear motor using traveling surface acoustic wave [6] and a linear ultrasonic motor using push-pull type L-B hybrid Langevin transducer with single foot [3]. Their linear movement speed of the fastest are 1527 mm/s, 1500 mm/s and 1280 mm/s respectively. If we only pay attention to thrust or loading ability, such as the square matrix type ultrasonic motor [7], a 2-DOF planar ultrasonic motor using longitudinal-bending hybrid transducer [5] and aultrasonic linear motor using longitudinal and bending multimode bolt-clamped Langevin type transducer [1] have the best performance. Their maximum thrust or loading are 142N, 103N and 100N respectively. If it focuses on energy efficiency, they are a linear piezoelectric motor driven by a single-phase signal [12], a multimode ultrasonic motor [10] and an ultrasonic linear motor using traveling surface acoustic wave [6]. Their minimum driving voltages are 16 V_p-p, 30 V_p-p and 80 V_p-p respectively. Due to the linear piezoelectric motors have superior performance, and they have a high use value in the precision mechanical systems. So in addition to the above the linear piezoelectric motors, in any form or performance of the linear piezoelectric motors are worth trying to develop. In addition, we, according to the rotary piezoelectric motor of mode shape, have the advantage of a high rotational speed and excellent performance [20]. We try to use the same mode shape coating method to produce a new linear piezoelectric motor, and hope the linear piezoelectric motor of mode shape also have a more superior performance with respect to the linear piezoelectric motor using normal shape coating, which is our motivation and main purpose in this paper.

2. The Function of Mode Shape and Effective Electrode Surface

In this study, the linear piezoelectric motor can be regarded as a like simple supported beam with pinned-pinned boundary conditions [20] [21], shown in Figure 1. So we can get the origin function of mode shape $\phi_n(\vec{x})$ of the linear piezoelectric motor as follows:
Figure 1. The origin functions of mode shape of the linear piezoelectric motors under pinned-pinned boundary conditions.

\[ \phi_\lambda (x) = \sin \frac{n \pi x}{l}, \quad 0 \leq x \leq 1. \]  

(1)

where the dimensionless eigenvalues \( \lambda_n \) is defined as:

\[ \lambda_n = n \pi; \quad n = 1, 2, 3, \ldots, \infty. \]  

(2)

And further we can get another function of the effective electrode surface \( \bar{F}P_x (x) \) from Equation (1) as follows or shown in Figure 2 and Table 2:

\[
\bar{F}P_x (x) = \begin{cases} 
\left[ \frac{F}{P_x (x)} \right]_{NS} = C_{NS} \\
\left[ \frac{F}{P_x (x)} \right]_{MS} = \frac{1}{\lambda_n^2} \frac{\partial^2 \phi_\lambda (x)}{\partial x^2}
\end{cases}
\]  

(3)

where the \( C_{NS} \) is defined as a constant. The subscript of NS and MS represent normal shape and mode shape.
3. The Composition and Operation Principle

According to the functions of the effective electrode surface or from Equation (3), we can design a series of linear piezoelectric motors, including the linear piezoelectric motors of normal shape and mode shape, as shown in Figure 3. For the linear piezoelectric motors of mode shape, we just take the first three functions of the mode shape and the effective electrode surface as the subject of research. As for the main components of the linear piezoelectric motor comprise two piezoelectric ceramics and an aluminum base of bench type. Which the polarization directions of the two piezoelectric ceramics are in pairs. When we operate the linear piezoelectric motor, only applied driving voltage ($V_3$) and resonance frequency ($f_r$) or proper loading, we can make linear motion of the piezoelectric motor, as shown in Figure 4. When the right membrane force is greater than the left side of the
Figure 3. The composition of the linear piezoelectric motors of normal shape and mode shape.

Figure 4. The operation principle and motion state of the linear piezoelectric motor of normal shape or mode shape.
membrane force, the piezoelectric motor will move to the right. On the contrary, the piezoelectric motor will then move to the left.

4. The Equations of Axial and Transverse Vibration

In order to distinguish differences of the linear piezoelectric motor of the normal shape and mode shape, we can simplify the equations of motion of 3D structure into the equations of motion of the two 1D structures. One of which is the equation of motion of the axial vibration direction, the other is the equation of motion of the transverse vibration direction as follow:

\[
\frac{\partial^2 N_1}{\partial x^2} = \rho h l \frac{\partial^2 u(x,t)}{\partial t^2},
\]

and

\[
\frac{\partial^2 M_1}{\partial x^2} = \rho h l \frac{\partial^2 w(x,t)}{\partial t^2},
\]

where the membrane force \((N_1)\) and of bending moment \((M_1)\) unit width are defined as:

\[
N_1 = A_1 \frac{\partial u}{\partial x} - \sum_{k=1}^{8} \int_{\epsilon} \left[ V_{1\epsilon} e_{1\epsilon} F P_1 \left( \bar{x} \right) \right] dx,
\]

and

\[
M_1 = D_1 \int_{\epsilon} \frac{\partial^2 \bar{w}}{\partial x^2} - \sum_{k=1}^{8} \int_{\epsilon} \left[ z V_{1\epsilon} e_{1\epsilon} F P_1 \left( \bar{x} \right) \right] dx.
\]

We can let Equation (1)-(3) & (6) (7) are substituted into Equation (4) & (5), and then after finishing, we can get the equations of motion by axial and transverse displacement of the linear piezoelectric motor of the normal shape and mode shape as follow:

\[
\left[ \frac{\partial^2 u(x,t)}{\partial x^2} = \frac{\rho h l}{A_1} \frac{\partial^2 u(x,t)}{\partial t^2} \right]_{NS},
\]

and

\[
\left[ \frac{\partial^2 w(x,t)}{\partial x^2} = \frac{\rho h l}{A_1} \frac{\partial^2 w(x,t)}{\partial t^2} + \frac{\Pi_1(t)}{A_1 b_{122} \lambda_3} \frac{\partial^4 \phi_2(x)}{\partial x^4} \right]_{MS}.
\]

and

\[
\left[ \frac{\partial^2 w(x,t)}{\partial x^2} + \frac{\rho h l^4}{D_1} \frac{\partial^2 w(x,t)}{\partial t^2} = 0 \right]_{NS},
\]

and

\[
\left[ \frac{\partial^2 \bar{w}(x,t)}{\partial x^2} + \frac{\rho h l^4}{D_1} \frac{\partial^2 \bar{w}(x,t)}{\partial t^2} = \Pi_1(t) \frac{\partial^4 \phi_2(x)}{\partial x^4} \right]_{MS}.
\]

According above the Equations (8)-(11), we can get the general solutions of axial and transverse vibration displacement \((\bar{u} \text{ and } \bar{w})\) of the linear piezoelectric motors of normal shape and mode shape can be expressed as follow:

\[
\left[ u(x,t) \right]_{NS} = \left[ U(x)e^{i\omega t} \right]_{NS} = \left[ \left( C_{w1} \sin \beta_3 x + C_{w2} \cos \beta_3 x \right)e^{i\omega t} \right]_{NS},
\]

\[
\left[ u(x,t) \right]_{MS} = \left[ U(x)e^{i\omega t} \right]_{MS} = \left[ C_{w1} \sin \beta_3 x + C_{w2} \cos \beta_3 x + U_\rho(x) \right]_{MS},
\]

and

\[
\bar{w}_{NS}(x,t) = \bar{w}_{NS}(x)e^{i\omega t} = \left[ C_{w1} \sin \beta_4 x + C_{w2} \cos \beta_4 x + C_{w3} \sin \beta_4 x + C_{w4} \cos \beta_4 x \right] e^{i\omega t},
\]

\[
\bar{w}_{MS}(x,t) = \bar{w}_{MS}(x)e^{i\omega t} = \left[ C_{w1} \sin \beta_4 x + C_{w2} \cos \beta_4 x + C_{w3} \sin \beta_4 x + C_{w4} \cos \beta_4 x + A_{w1}\phi_4(x) \right] e^{i\omega t},
\]
where the definition of constants or symbols in the above Equations (4)-(15) as follow:

\[ A_1 = \sum_{k=1}^{n} (hc_{11})_k, \]

\[ A_n = \overline{\lambda}_{nn} \Pi_1, \]

\[ D_{ii} = \frac{1}{3} \sum_{k=1}^{n} \left[ c_{11} \left( z_k - z_{k-1} \right) \right], \]

\[ h_k = z_k - z_{k-1}, \]

\[ \rho h = \sum_{k=1}^{n} \rho_k h_k, \]

\[ \overline{\lambda}_i^I = \frac{\rho h l \omega_i^2}{D_{11}} = \frac{4 \rho h l^2 \pi^2 f_i^2}{D_{11}}, \]

\[ \overline{\lambda}_i^L = \frac{\rho h l \omega_i^2}{D_{11}} = \frac{4 \rho h l^2 \pi^2 f_i^2}{D_{11}}, \]

\[ \bar{\beta}_i = \frac{l \omega_i}{\sqrt{A_1}}, \]

\[ \Pi_3 (t) = \Pi_3 e^{j\omega t} = h_{pzt} e_{31} V_s e^{j\omega t}. \]

where in above the symbols of \( A_{11}, A_n, c_{11}, D_{11}, f_i, f_n, h, t, U, u, V, w, x, z, \rho, \omega, \omega_n, \overline{\lambda}, \overline{\lambda}_n, \bar{\beta}_i \) and \( \Pi_3 \) are defined as the membrane stiffness constant per unit width, amplitude, Young’s modulus, bending stiffness constant per unit width, an arbitrary frequency, the resonance frequency, total height or thickness of piezoelectric ceramic or aluminum base, time, the axial displacement dependent on the axial coordinate, the axial displacement dependent on the axial coordinate and time, the transverse driving voltage, the transverse displacement dependent on the axial coordinate, the transverse displacement dependent on the axial coordinate and time, axial coordinate, transverse coordinate, density, the angle velocity of arbitrary frequency, the angle velocity of resonance frequency, the eigenvalues of arbitrary frequency of transverse direction, the eigenvalues of resonance frequency of transverse direction, the eigenvalues of arbitrary frequency of axial direction and the electric moment. Which \( C_{np} (p = 1 \sim 4) \) and \( C_{nq} (q = 1 \sim 2) \) represent undetermined coefficients of transverse and axial direction. Where the eigenvalues \( \overline{\lambda}_i \neq \lambda_{nn} \) and \( i \in R \) and \( n \in I \).

Where above undetermined coefficients can be determined by the following electro-mechanical boundary conditions:

\[ [\overrightarrow{u} (0,t) = -N_{iL}/A_{11}; \overrightarrow{u} (1,t) = -N_{iR}/A_{11} ]_{NS}, \]

\[ [\overrightarrow{w} (0,t) = -N_{iL}/A_{11}; \overrightarrow{w} (1,t) = -N_{iR}/A_{11} ]_{NS} \]

and

\[ [\overrightarrow{w} (0,t) = 0; \overrightarrow{w} (0,t) = M_{iL}/D_{11}; \overrightarrow{w} (1,t) = 0; \overrightarrow{w} (1,t) = M_{iR}/D_{11} ]_{NS}, \]

\[ [\overrightarrow{w} (0,t) = 0; \overrightarrow{w} (0,t) = M_{iL}/D_{11}; \overrightarrow{w} (1,t) = 0; \overrightarrow{w} (1,t) = M_{iR}/D_{11} ]_{MS}, \]

where

\[ N_{iL} = N_{iL}^F + N_{iL}^M = C_{NS} \Pi_3 \frac{h_{pzt}}{F_{\mu}}; N_{iR} = N_{iR}^F + N_{iR}^M = C_{NS} \Pi_3 \frac{h_{pzt}}{F_{\mu}} \]
Another the frictional force is defined as follow:

\[ F_{\beta L} = \mu_k \left( \frac{a}{l} W_{\text{mass}} + \frac{1}{2} W_{\text{net}} \right); \quad F_{\beta R} = \mu_k \left( \frac{l-a}{l} W_{\text{mass}} + \frac{1}{2} W_{\text{net}} \right), \]

where \( F_{\beta L}, F_{\beta R}, M_{1L}, M_{1R}, N_{1L} \) and \( N_{1R} \) represent the frictional force per unit width of left side, the frictional force per unit width of right side, the bending moment per unit width of left side, the bending moment per unit width of right side, the membrane force per unit width of left side and the membrane force per unit width of right side. And \( a, W_{\text{mass}}, W_{\text{net}} \) and \( \mu_k \) represent the intercept, mass or loading per unit width, net weight per unit width of the piezoelectric motor and coefficient of dynamic friction. Which \( h_{1L} \) and \( h_{1R} \) represent the centroid of the linear piezoelectric motor and the intercept of the piezoelectric ceramics. The superscript of \( E \) and \( M \) represent the electrical and mechanical.

Because the functions of mode shape are equal to zero under pinned-pinned boundary conditions as:

\[ \left. \frac{\partial \phi_1(x)}{\partial x} \right|_{x=0} = \left. \frac{\partial^2 \phi_1(x)}{\partial x^2} \right|_{x=0} = \left. \frac{\partial^2 \phi_2(x)}{\partial x^2} \right|_{x=0} = 0 \]

So the Equation (30) and Equation (32) can be rewritten as follows:

\[ N_{1L} = N_{1L}^E + N_{1L}^M \]

\[ M_{1L} = M_{1L}^E + M_{1L}^M \]

\[ M_{1R} = M_{1R}^E + M_{1R}^M \]

Let Equations (25)-(36) are substituted into Equations (12)-(15), we can get the solution of the axial and transverse vibration displacement of the first three modes of the linear piezoelectric motors as follow:
Let Equations (35)-(41) be substituted into Equations (12)-(15), we can obtain the particular solutions of the transverse and axial vibration displacement of the linear piezoelectric motor as follows:

\[
\begin{align*}
[u(\vec{x},t)]_{\text{NS}} &= \left[1 \over A_1\beta_i \left( {N_{1R} - N_{1L} \cos \beta_i \over \sin \beta_i} \right) \cos \beta_i \sqrt{x} - N_{1L} \sin \beta_i \sqrt{x} \right] e^{i\omega t}, \\
[u(\vec{x},t)]_{\text{MS}} &= \left[1 \over A_1\beta_i \left( {N_{1R} - N_{1L} \cos \beta_i \over \sin \beta_i} \right) \cos \beta_i \sqrt{x} - N_{1L} \sin \beta_i \sqrt{x} \right] + \sqrt{\Pi_1 \beta_i \over 2A_1 \rho_{PZT}} \sqrt{x} e^{i\omega t},
\end{align*}
\]  

(42)

(43)

and

\[
\begin{align*}
\bar{w}_{\text{NS}}(\vec{x},t) &= {1 \over 2D_1\beta_i^2} \left[ \left( {M_{1R} - M_{1L} \cosh \beta_i \over \sinh \beta_i} \right) \sinh \beta_i \sqrt{x} + \left( {M_{1L} \cosh \beta_i - M_{1R} \over \sin \beta_i} \right) \cosh \beta_i \sqrt{x} \right] e^{i\omega t}, \\
\bar{w}_{\text{MS}}(\vec{x},t) &= \left[ \left( {M_{1R} - M_{1L} \cosh \beta_i \over 2D_1\beta_i^2} \right) \sinh \beta_i \sqrt{x} + \left( {M_{1L} \cosh \beta_i - M_{1R} \over 2D_1\beta_i} \right) \cosh \beta_i \sqrt{x} \right] \left[ {\Pi_1 \beta_i^2 \over 2A_1 \rho_{PZT}} \right] e^{i\omega t}.
\end{align*}
\]  

(44)

(45)

Further, we can simplify Equations (42)-(45) as follows:

\[
\begin{align*}
[u(\vec{x},t)]_{\text{NS}} &= \bar{U}_{\text{NS}} \sin(\omega t + \Phi), \\
[u(\vec{x},t)]_{\text{MS}} &= \bar{U}_{\text{MS}} \sin(\omega t + \Phi),
\end{align*}
\]  

(46)

(47)

and

\[
\begin{align*}
[\bar{w}(\vec{x},t)]_{\text{NS}} &= \bar{W}_{\text{NS}} \cos(\omega t + \Phi), \\
[\bar{w}(\vec{x},t)]_{\text{MS}} &= \bar{W}_{\text{MS}} \cos(\omega t + \Phi),
\end{align*}
\]  

(48)

(49)

where \( \Phi \) is defined as the driving phase angle.

Therefore, we can once again get the equations of elliptical trajectory of the linear piezoelectric motor of normal shape and mode shape at contact points on both sides from above Equations (46)-(49), as follow or shown in Figure 4:

\[
\left( {\bar{u} \over \bar{U}} \right)_{\text{NS}}^2 + \left( {\bar{w} \over \bar{W}} \right)_{\text{NS}}^2 = 1,
\]  

(50)

and

\[
\left( {\bar{u} \over \bar{U}} \right)_{\text{MS}}^2 + \left( {\bar{w} \over \bar{W}} \right)_{\text{MS}}^2 = 1.\]  

(51)

At this point we can see the difference in the linear motors of normal shape and mode shape from the solutions of displacement. Then we will be to test their differences or gains by the case study of theoretical analysis, computer simulation and experiments.
5. Special Case Study of Theoretical Analysis, Simulation Analysis and Experiments

We have to understand the differences and gain between the linear piezoelectric motors of the normal shape and mode shape in this study. We will try to verify the differences and gain of the linear piezoelectric motors through theoretical analysis, simulation analysis and experiments. Where in the associated electrical and mechanical properties of the linear piezoelectric motors in special case study is shown in Table 3.

The first is theoretical analysis in this special case study, which is as follows:

(5-1-1) Try to find the approximate solution of the transverse displacement of the linear piezoelectric motors of the normal shape and mode shape in the special case study. We can take to understand their difference and gain under condition of the normal shape and different mode shape electrode coating.

(5-1-2) Try to find the approximate solution of the axial displacement of the linear piezoelectric motors of the normal shape and mode shape in the special case study. We can further understand the impact of the axial or linear movement under conditions of the normal shape and different mode shape electrode coating or the above modal vibration.

(5-1-3) Try to understand the impact of the axial or linear movement of the linear piezoelectric motors of the normal shape and mode shape under conditions of the different loading (or mass) and positions.

Second is simulation analysis by ANSYS code (its modal analysis under different driving conditions shown in Figures 5-10, its main analytical work as follows:

(5-2-1) Try to find the vibration modal of the linear piezoelectric motors of the normal shape and mode shape in the special case study.

(5-2-2) Try to find the axial (or linear) and transverse displacement from the above vibration modal under condition of net weight.

(5-2-3) Try to find the axial (or linear) and transverse displacement under conditions of different loading, position and steady state.

(5-3-1) Finally the experimental work (its prototype and structure shown in Figure 11, Figure 12 as follows:

(5-3-2) Try to find the maximum axial (or linear) speed of linear piezoelectric motors of the normal shape and mode shape under condition of net weight.

(5-3-3) Try to find the maximum axial (or linear) speed of linear piezoelectric motors of the normal shape and mode shape under condition of the different loading (or mass) and position.

6. Results and Discussion

According to the results of theoretical analysis, simulation analysis and experiments, we found:

1) Shown in Figures 13-15, we have found that the change in axial displacement or velocity of more focus and smooth of the linear piezoelectric motors of mode shape with respect to the linear piezoelectric motor of normal shape by theoretical analysis under conditions of the first three vibration modal or driving frequency, 180 Vp-p driving voltage, net weight, frequency spacing of 1 Hz and the first three eigenvalues.

2) Shown in Figure 16, we have found that the gain in transverse displacement or velocity of the linear piezoelectric motors of mode shape is much larger than the linear piezoelectric motor of normal shape by theoretical analysis under conditions of the first three vibration modal or driving frequency, 180 Vp-p driving voltage, net weight, frequency spacing of 1 Hz and the first three eigenvalues.

Figure 18. The dimensionless axial displacement or velocity relative to the position of loading or mass of the linear piezoelectric motors of the normal shape and mode shape by simulation analysis under conditions of 180 V_{p-p} driving voltage, 25 gw loading and the first three vibration modal.

Figure 19. The axial displacement velocity relative to the position of loading or mass of the linear piezoelectric motors of the normal shape and mode shape by experiments under conditions of 180 V_{p-p} driving voltage, 25 gw loading, and the driving frequency of the first three vibration modal.

under conditions of different position of loading or mass, 180 V_{p-p} driving voltage, 25 gw loading and the first three vibration modes or driving frequency. Wherein the linear piezoelectric motor of mode shape 3 having the fastest axial velocity, which is about ~48 mm/s and 48 mm/s under conditions of 180 V_{p-p} driving voltage, 21.2
kHz driving frequency (the third vibration modal), 25 gw loading and the position of loading or mass at $x = 5$ mm & 45 mm respectively. And its axial velocity is about 1.4 times the linear piezoelectric motor of normal shape under the same conditions.

7. Conclusion

According to the results of theoretical analysis, simulation analysis and experiments, we have found that the change in axial displacement or velocity of the linear piezoelectric motors of mode shape is more focus and smooth than the linear piezoelectric motor of normal shape. We also have found that the gain in axial and transverse displacement or velocity of the linear piezoelectric motors of mode shape is much larger than the linear piezoelectric motor of normal shape. We have further found that the axial velocity of the linear piezoelectric motors of mode shape is much larger than the linear piezoelectric motor of normal shape under condition of eccentric loading or mass. We also have found that the linear piezoelectric motors of normal shape and mode shape cannot move faster, when the state of net weight or the loading (or mass) placed at the center position of the motors. When the loading or mass is farther away from the center, it’s moving faster. And we also have found that the placement of the loading or mass can change the direction of axial movement of the motors. Overall, for all motors, the gain of the axial velocity of the third vibration modal is much larger than the first and second vibration modal. From the above results, we have found that the transverse mode shape coating has a positive effect on the axial displacement. That is, the transverse mode shape coating can make energy more concentrated with respect to the normal shape coating, so that axial displacement can more quickly move.

Acknowledgements

This study can be finished smoothly, I especially want to thank MOST of Taiwan of ROC sponsor on funding, (Project No.: MOST104-2221-E-230-016).
